exercise

use 1-bit predictor on this loop

executed in outer loop (not shown) many, many times

what is the conditional branch misprediction rate?

```
int i = 0;
while (true) {
  if (i % 3 == 0) goto next;
  ...
next:
  i += 1;
  if (i == 50) break;
}
```

1-cycle fetch?

assumption so far:

1 cycle to fetch instruction + identify if jmp, etc.

often not really practical

especially if:

- complex machine code format
- many pipeline stages
- more complex instruction cache
- (future idea) fetching 2+ instructions/cycle

branch target buffer

what if we can't decode LABEL from machine code for `jmp LABEL` or `jle LABEL` fast?

- will happen in more complex pipelines

what if we can't decode that there's a RET, CALL, etc. fast?

BTB: cache for branch targets

```

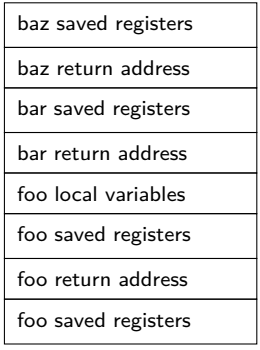
predicting ret: ministack of return addresses

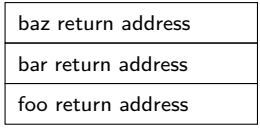
predicting ret — ministack in processor registers

push on ministack on call; pop on ret

ministack overflows? discard oldest, mispredict it later

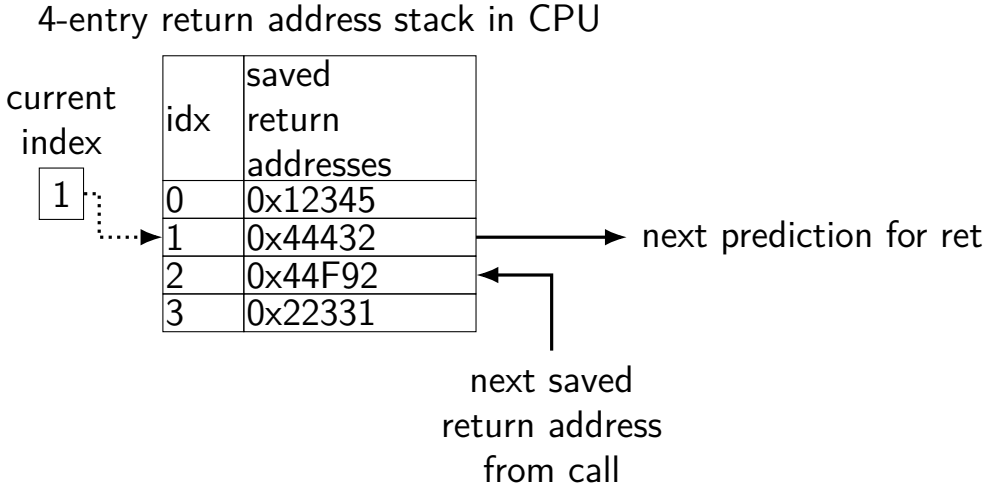


stack in memory



(partial?) stack in CPU registers

4-entry return address stack



on `call`: increment index, save return address in that slot

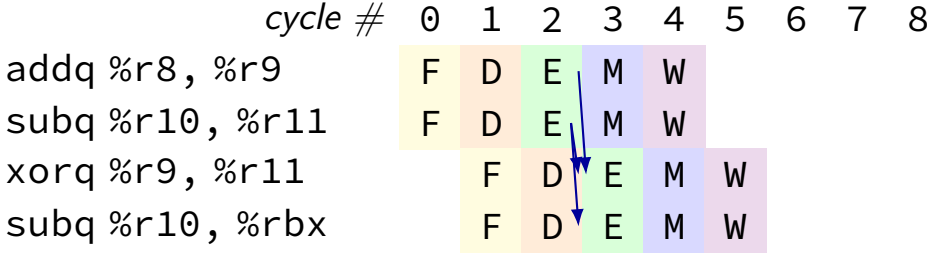
on `ret`: read prediction from index, decrement index

beyond pipelining: multiple issue

start more than one instruction/cycle

multiple parallel pipelines; many-input/output register file

hazard handling much more complex



beyond pipelining: out-of-order

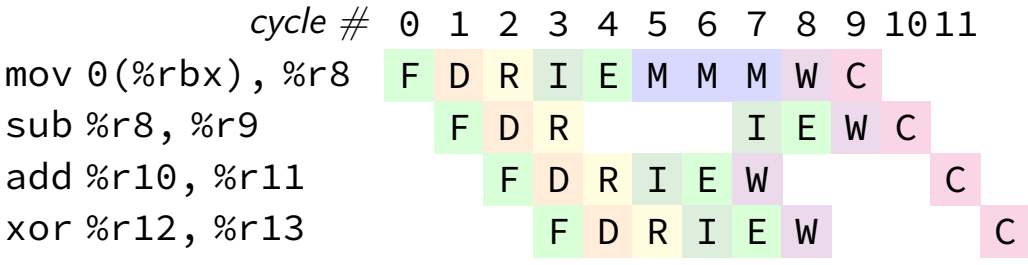
find later instructions to do instead of stalling

lists of available instructions in pipeline registers

- take any instruction with available values

provide illusion that work is still done in order

- much more complicated hazard handling logic



interlude: real CPUs

modern CPUs:

execute multiple instructions at once

execute instructions out of order — whenever values available

out-of-order and hazards

out-of-order execution makes hazards harder to handle

problems for forwarding:

- value in last stage may not be most up-to-date
- older value may be written back before newer value?

problems for branch prediction:

- mispredicted instructions may complete execution before squashing

which instructions to dispatch?

- how to quickly find instructions that are ready?

out-of-order and hazards

out-of-order execution makes hazards harder to handle

problems for forwarding:

- value in last stage may not be most up-to-date
- older value may be written back before newer value?

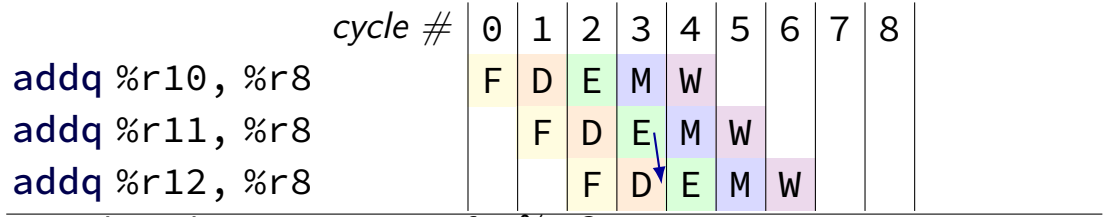
problems for branch prediction:

- mispredicted instructions may complete execution before squashing

which instructions to dispatch?

- how to quickly find instructions that are ready?

read-after-write examples (1)



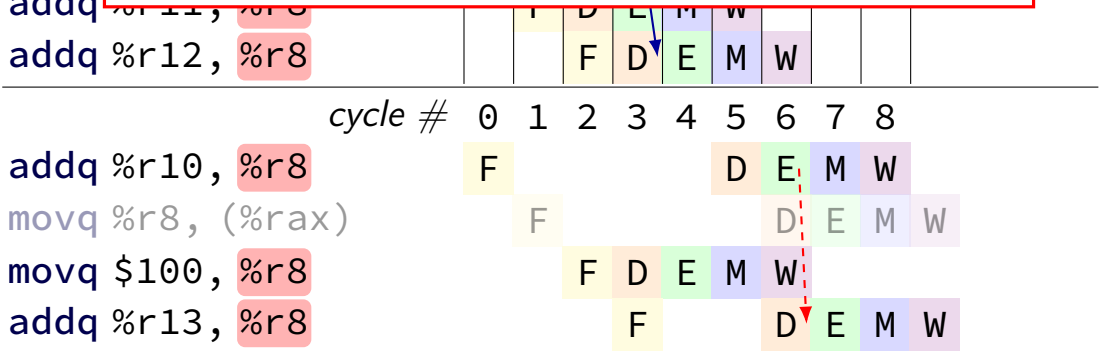
normal pipeline: two options for %r8?

choose the one from *earliest stage*

because it's from the most recent instruction

read-after-write examples (1)

out-of-order execution:
%r8 from earliest stage might be from *delayed instruction*
can't use same forwarding logic



register version tracking

goal: track different versions of registers

out-of-order execution: may compute versions at different times

only forward the correct version

strategy for doing this: preprocess instructions represent version info

makes forwarding, etc. lookup easier

rewriting hazard examples (1)

`addq %r10, %r8`	`addq %r10,` $\texttt{\%r8}_{\texttt{v1}} \rightarrow \texttt{\%r8}_{\texttt{v2}}$
`addq %r11, %r8`	`addq %r11,` $\texttt{\%r8}_{\texttt{v2}} \rightarrow \texttt{\%r8}_{\texttt{v3}}$
`addq %r12, %r8`	`addq %r12,` $\texttt{\%r8}_{\texttt{v3}} \rightarrow \texttt{\%r8}_{\texttt{v4}}$

read different version than the one written

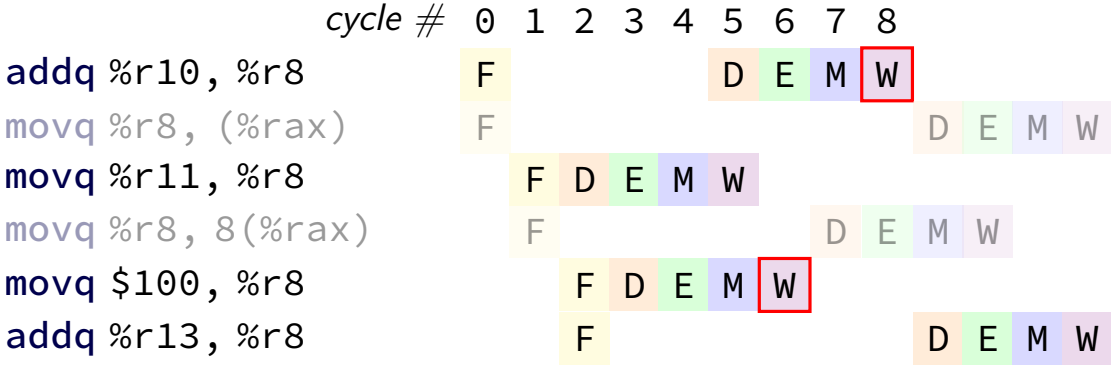
- represent with three argument psuedo-instructions

forwarding a value? must match version *exactly*

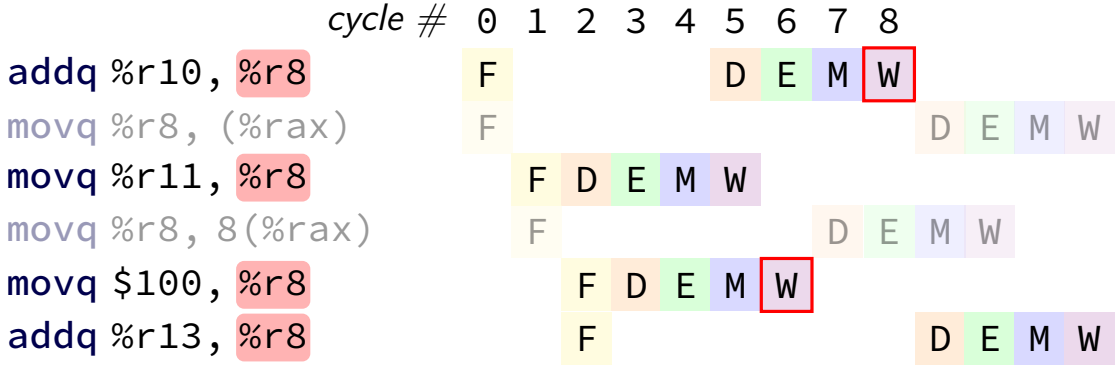
for now: version numbers

later: something simpler to implement

write-after-write example

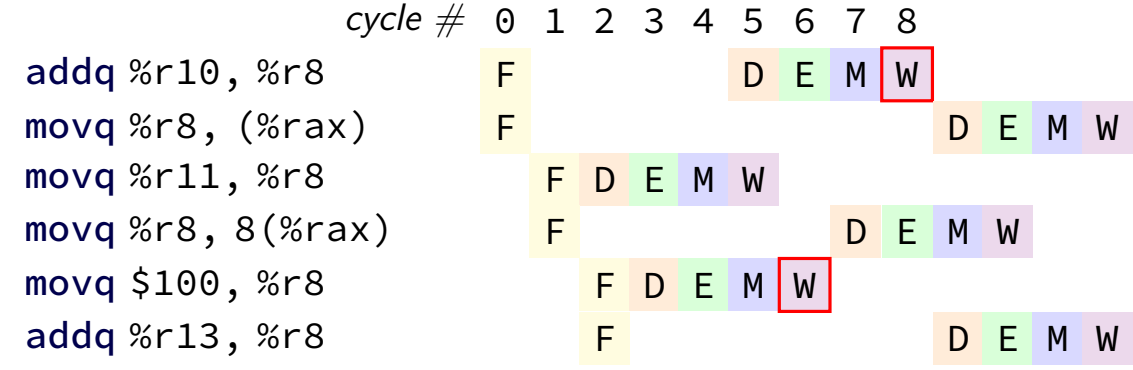


write-after-write example



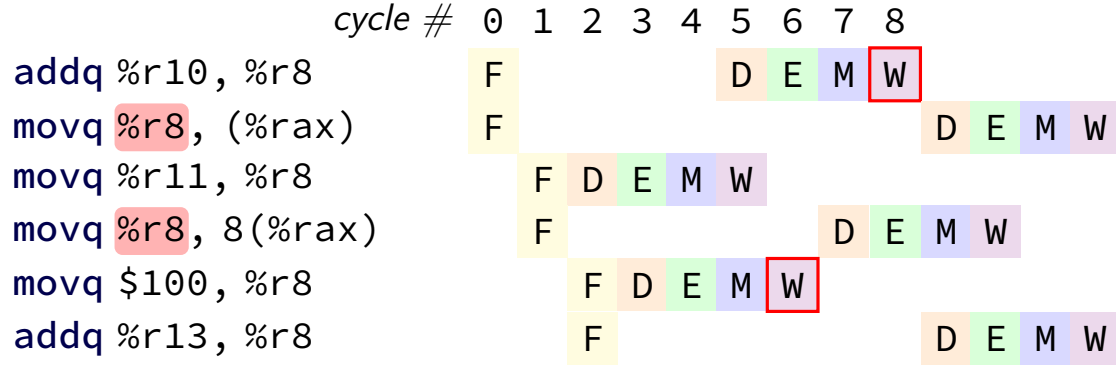
out-of-order execution:
if we don't do something, newest value could be overwritten!

write-after-write example



two instructions that haven't been started could need *different versions* of %r8!

write-after-write example



keeping multiple versions

for write-after-write problem: need to keep copies of multiple versions

both the new version and the old version needed by delayed instructions

for read-after-write problem: need to distinguish different versions

solution: have lots of extra registers

...and assign each version a new 'real' register

called register renaming

register renaming

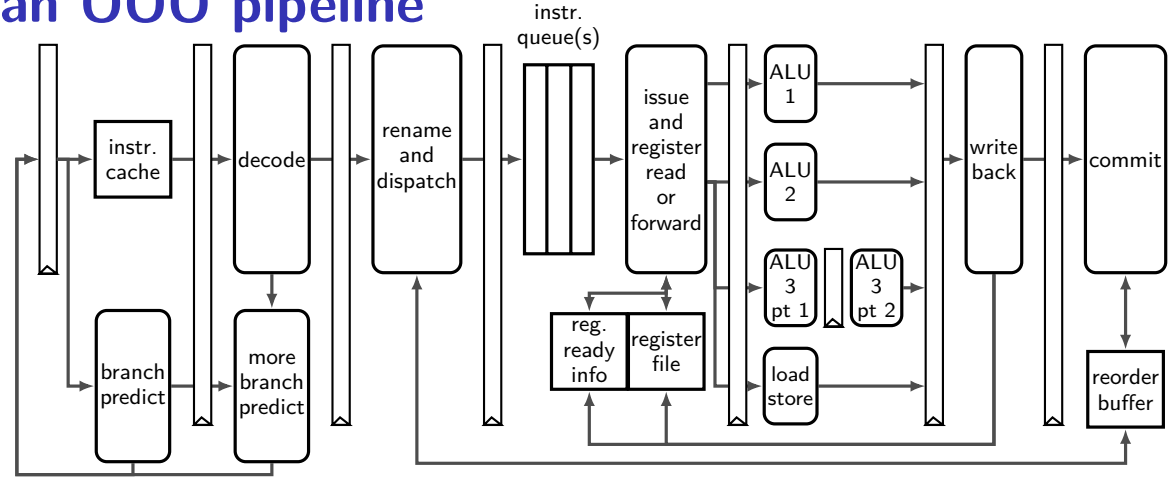
rename *architectural registers* to *physical registers*

different physical register for each version of architectural

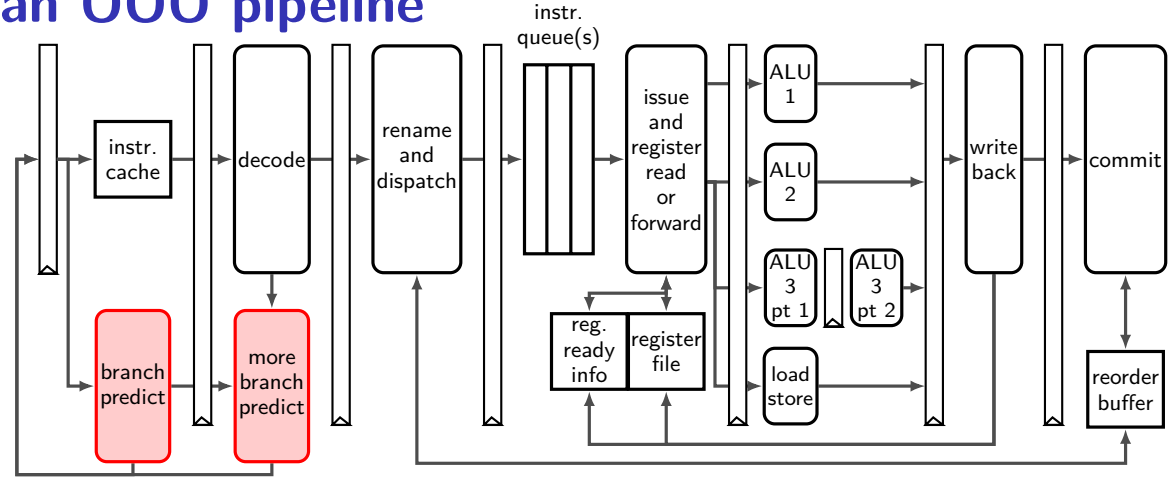
track which physical registers are ready

compare physical register numbers to do forwarding

an OOO pipeline

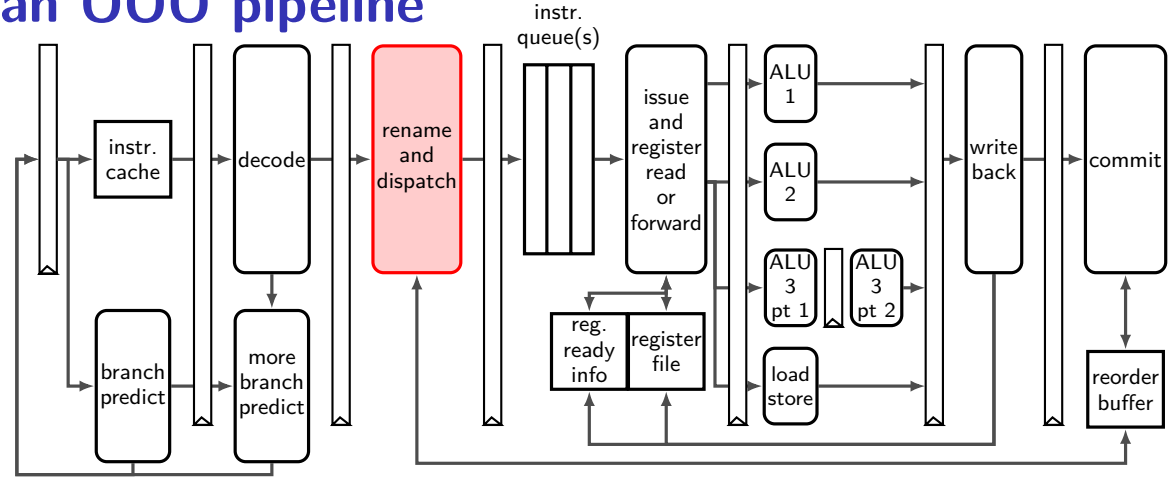


an OOO pipeline



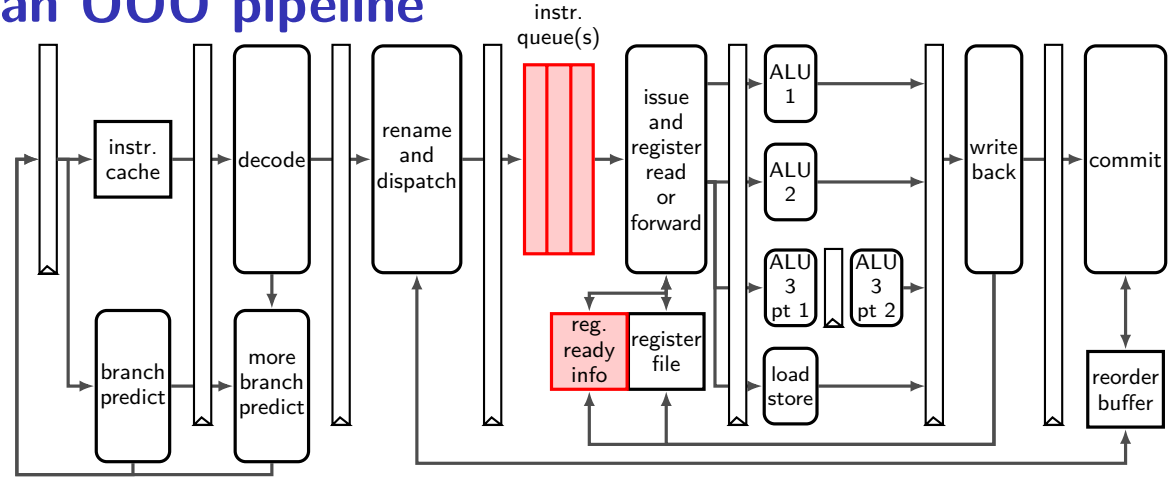
branch prediction needs to happen before instructions decoded
done with cache-like tables of information about recent branches

an OOO pipeline



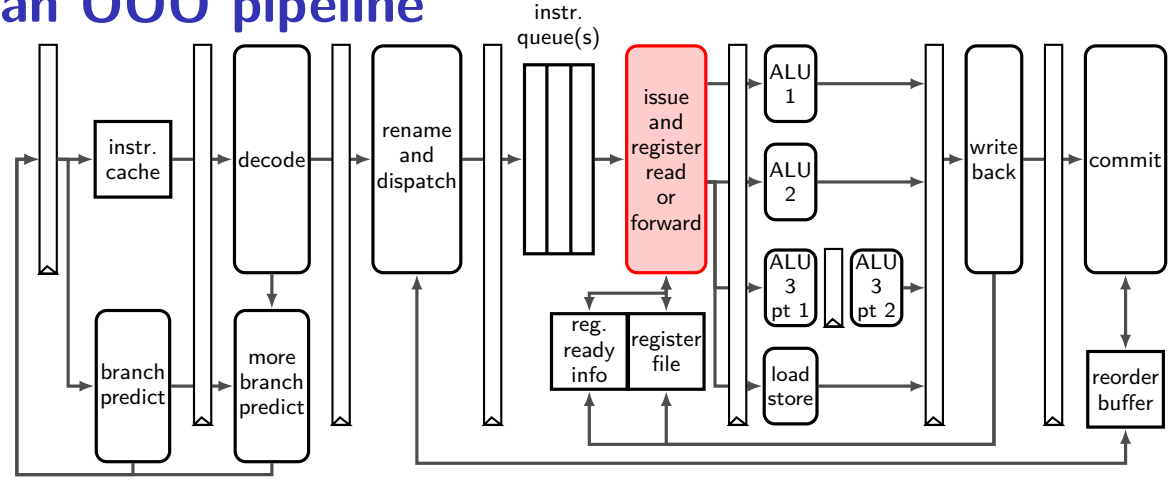
register renaming done here
stage needs to keep mapping from architectural to physical names

an OOO pipeline



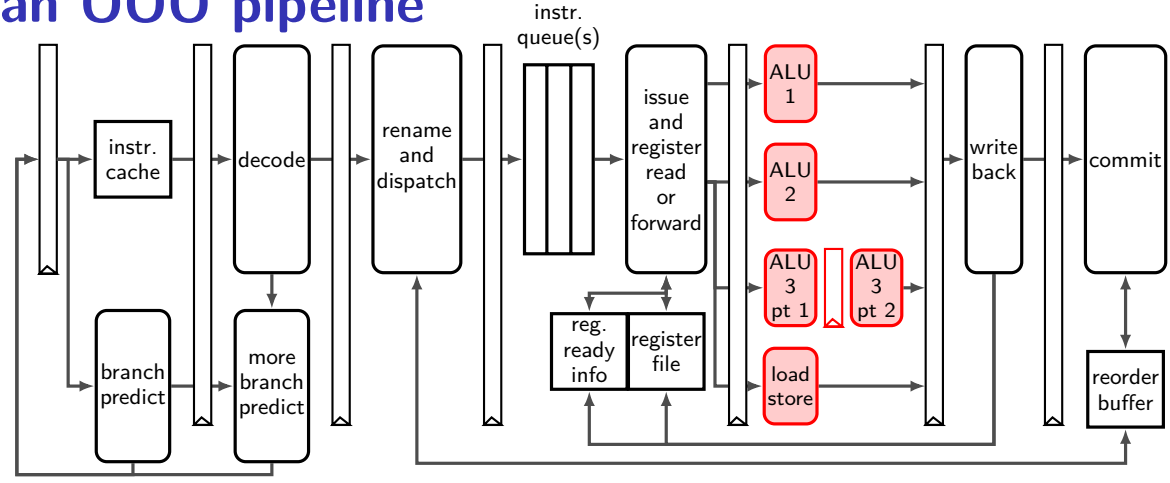
instruction queue holds pending renamed instructions combined with register-ready info to *issue* instructions (issue = start executing)

an OOO pipeline



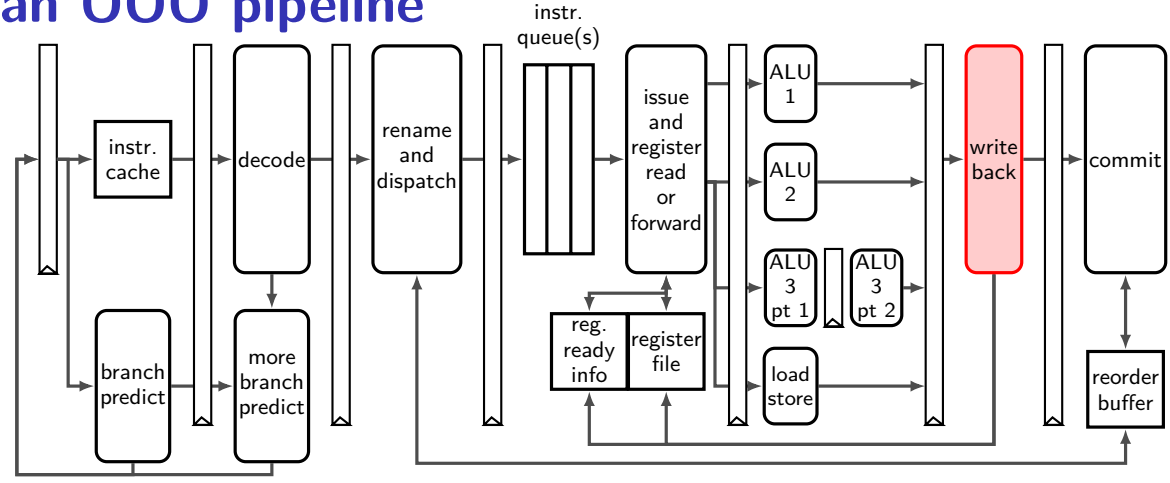
read from much larger register file and handle forwarding
register file: typically read 6+ registers at a time
(extra data paths wires for forwarding not shown)

an OOO pipeline



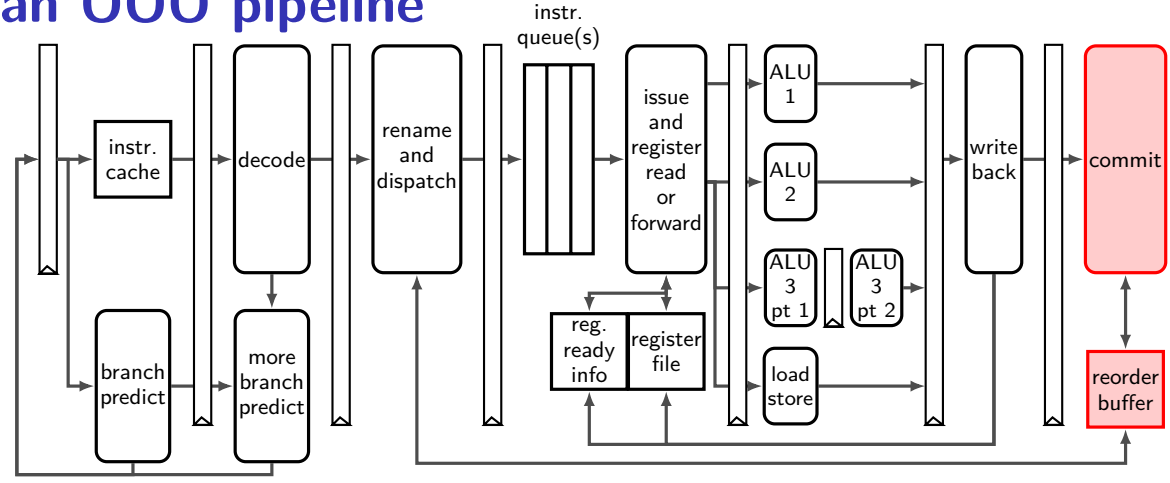
many *execution units* actually do math or memory load/store
some may have multiple pipeline stages
some may take variable time (data cache, integer divide, ...)

an OOO pipeline



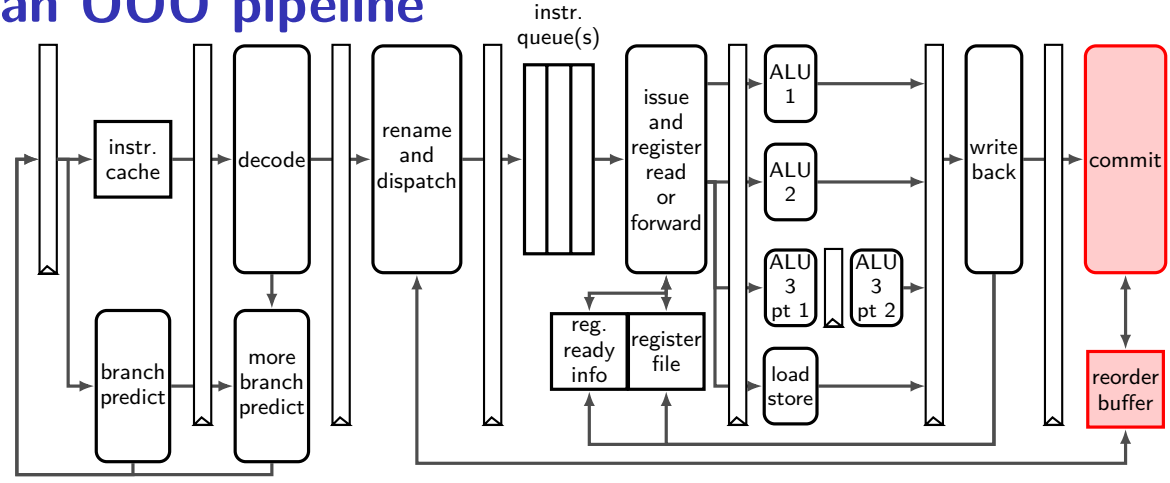
writeback results to physical registers
register file: typically support writing 3+ registers at a time

an OOO pipeline



new commit (sometimes *retire*) stage finalizes instruction
figures out when physical registers can be reused again

an OOO pipeline



commit stage also handles branch misprediction
reorder buffer tracks enough information to undo mispredicted instrs.

an OOO pipeline diagram

cycle #	0	1	2	3	4	5	6	7	8	9	10	11
`addq %r01, %r05`	F	D	R	I	E	W	C

assume 1 cycle/access

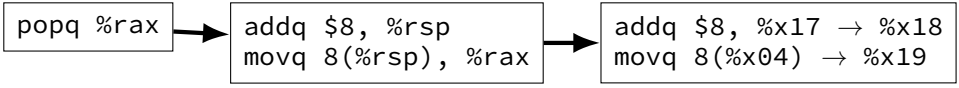
register renaming: missing pieces

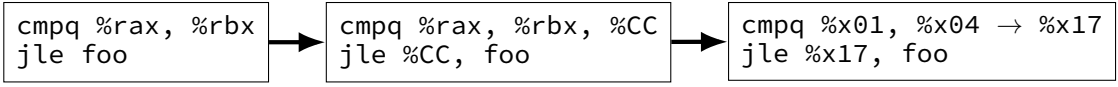
what about "hidden" inputs like `%rsp`, condition codes?

one solution: translate to intructions with additional register parameters

- making %rsp explicit parameter
- turning hidden condition codes into operands!

bonus: can also translate complex instructions to simpler ones





an OOO pipeline diagram

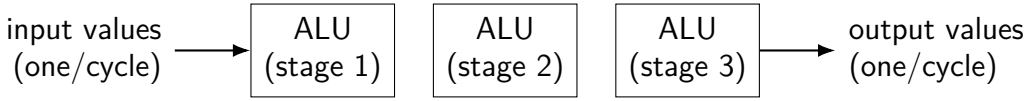
execution units AKA functional units (1)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes pipelined:

(here: 1 op/cycle; 3 cycle latency)



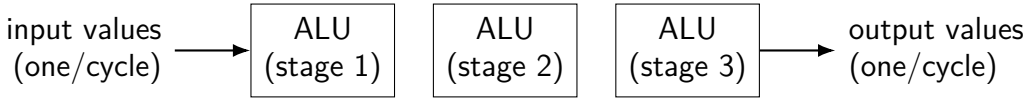
execution units AKA functional units (1)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes pipelined:

(here: 1 op/cycle; 3 cycle latency)



exercise: how long to compute $A \times (B \times (C \times D))$?

execution units AKA functional units (2)

where actual work of instruction is done

e.g. the actual ALU, or data cache

sometimes unpipelined:

OOO limitations

can't always find instructions to run

- plenty of instructions, but all depend on unfinished ones
- programmer can adjust program to help this

need to track all uncommitted instructions

- can only go so far ahead
- e.g. Intel Skylake: 224-entry reorder buffer, 168 physical registers

branch misprediction has a big cost (relative to pipelined)

- e.g. Intel Skylake: up to approx. 16 cycles (v. 2 for simple pipelined CPU)

OOO limitations

can't always find instructions to run

- plenty of instructions, but all depend on unfinished ones
- programmer can adjust program to help this

need to track all uncommitted instructions

- can only go so far ahead
- e.g. Intel Skylake: 224-entry reorder buffer, 168 physical registers

branch misprediction has a big cost (relative to pipelined)

- e.g. Intel Skylake: up to approx. 16 cycles (v. 2 for simple pipelined CPU)

some performance examples

```
example1:
    movq $10000000000, %rax
loop1:
    addq %rbx, %rcx
    decq %rax
    jge loop1
    ret
```

about 30B instructions

my desktop: approx 2.65 sec

```
example2:
    movq $10000000000, %rax
loop2:
    addq %rbx, %rcx
    addq %r8, %r9
    decq %rax
    jge loop2
    ret
```

about 40B instructions

my desktop: approx 2.65 sec

    decq %rax
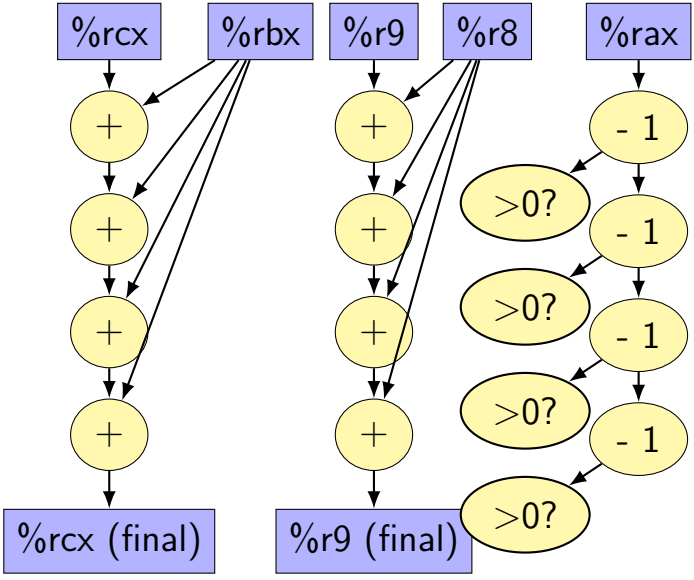
    jge loop2
    ret
```

about 40B instructions

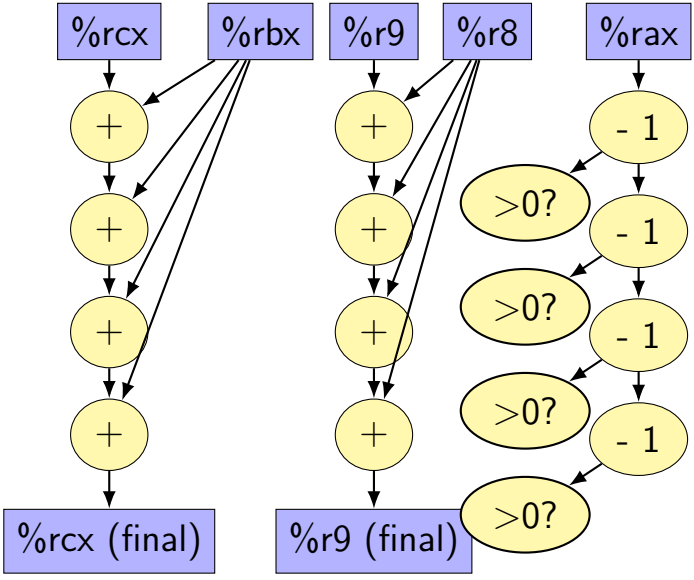
my desktop: approx 2.65 sec

data flow model and limits (1)



```
loop2:
    addq %rbx, %rcx
    addq %r8, %r9
    decq %rax
    jge loop2
```

data flow model and limits (1)



each yellow box = instruction

arrows = dependences

instructions only executed when dependencies ready

reassociation

with pipelined, 5-cycle latency multiplier; how long does each take to compute?

$((a \times b) \times c) \times d$

```
imulq %rbx, %rax
imulq %rcx, %rax
imulq %rdx, %rax
```

$(a \times b) \times (c \times d)$

```
imulq %rbx, %rax
imulq %rcx, %rdx
imulq %rdx, %rax
```

reassociation

with pipelined, 5-cycle latency multiplier; how long does each take to compute?

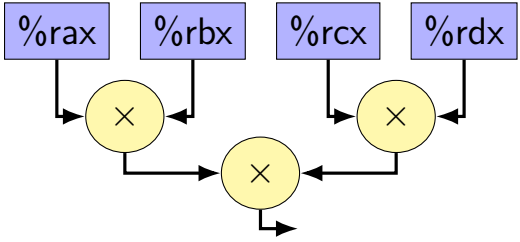
$(a \times b) \times (c \times d)$

```
imulq %rbx, %rax
imulq %rcx, %rdx
imulq %rdx, %rax
```



Intel Skylake OOO design

2015 Intel design — codename 'Skylake'

94-entry instruction queue-equivalent

168 physical integer registers

168 physical floating point registers

4 ALU functional units
- but some can handle more/different types of operations than others

2 load functional units
- but pipelined: supports multiple pending cache misses in parallel

1 store functional unit

224-entry reorder buffer
- determines how far ahead branch mispredictions, etc. can happen

backup slides

backup slides

indirect branch prediction

`jmp *%rax` or `jmp *(%rax, %rcx, 8)`

BTB can provide a prediction

but can do better with more context

example—predict based on other recent computed jumps

- good for polymophic method calls

table lookup with Hash(last few jmps)
instead of Hash(this jmp)

an OOO pipeline diagram

…and discard all the mispredicted instructions (without committing them)

better? alternatives

can take snapshots of register map on each branch

- don't need to reconstruct the table
- (but how to efficiently store them)

can reconstruct register map before we commit the branch instruction

- need to let reorder buffer be accessed even more?

can track more/different information in reorder buffer

handling memory accesses?

one idea:

list of done + uncommited loads+stores

execute load early + double-check on commit

- have data cache watch for changes to addresses on list
- if changed, treat like branch misprediction

loads check list of stores so you read back own values

actually finish store on commit

- maybe treat like branch misprediction if conflict?

the open-source BROOM pipeline

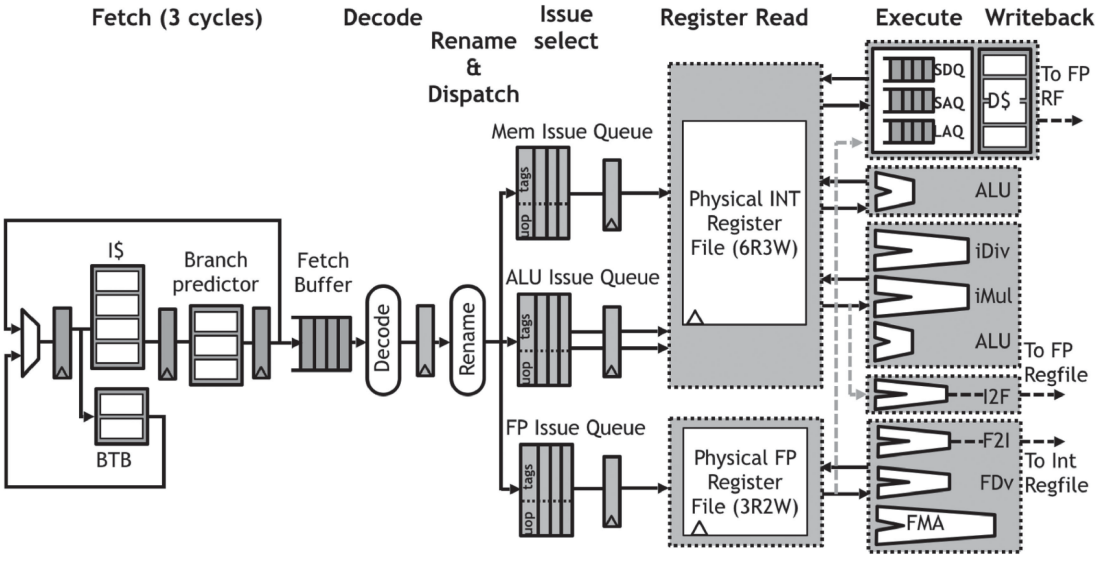

Figure from Celio et al., "BROOM: An Open Source Out-Of-Order Processor With Resilient Low-Voltage Operation in 28-nm CMOS"

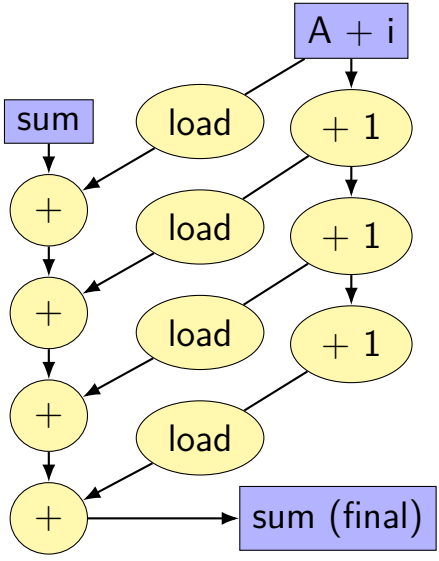
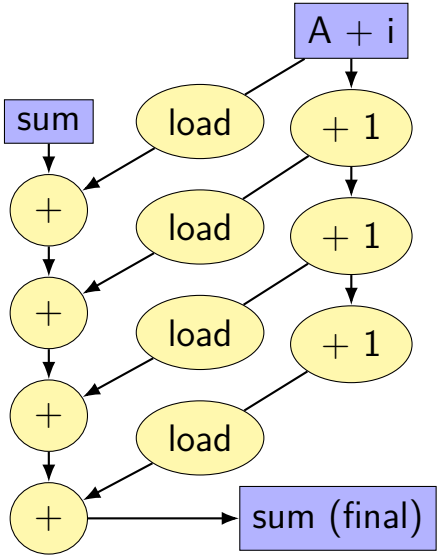
data flow model and limits



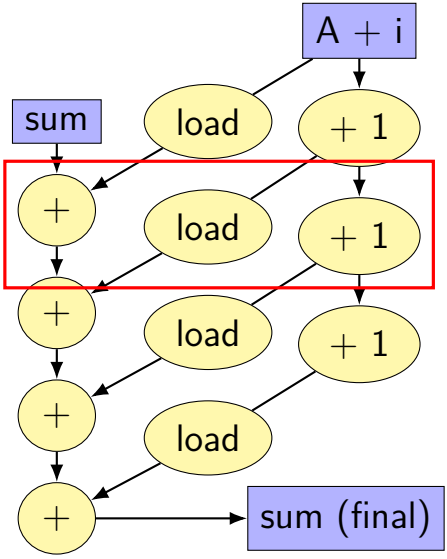
```
for (int i = 0; i < N; i += K) {
    sum += A[i];
    sum += A[i+1];
    ...
}
```

data flow model and limits



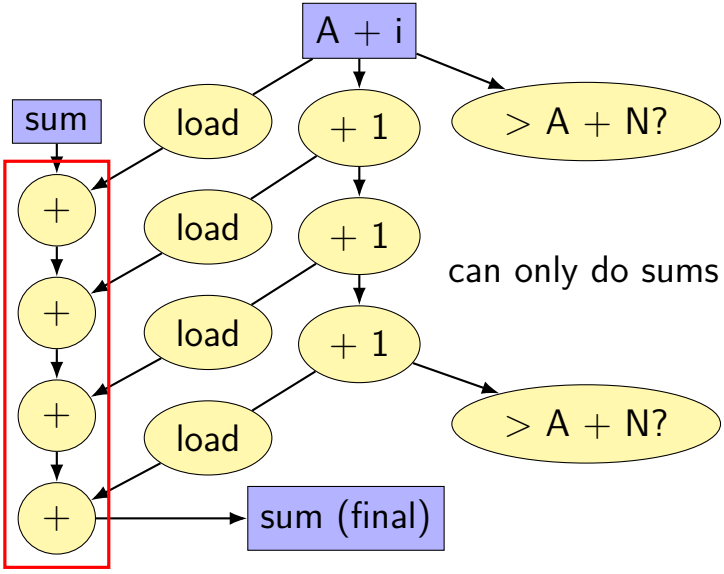
each yellow box = instruction
arrows = dependences
instructions only executed when dependencies

data flow model and limits



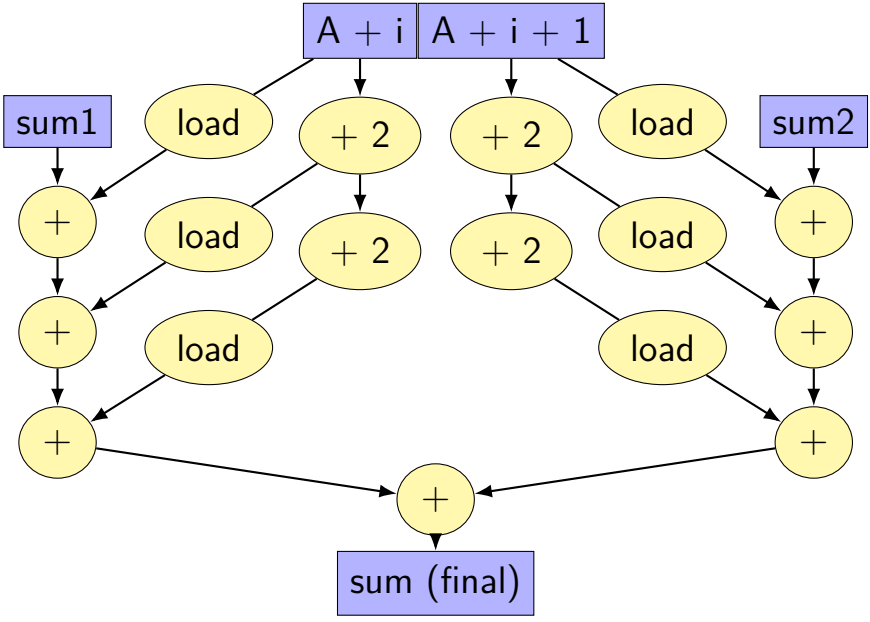
three ops/cycle (if each one cycle)

data flow model and limits

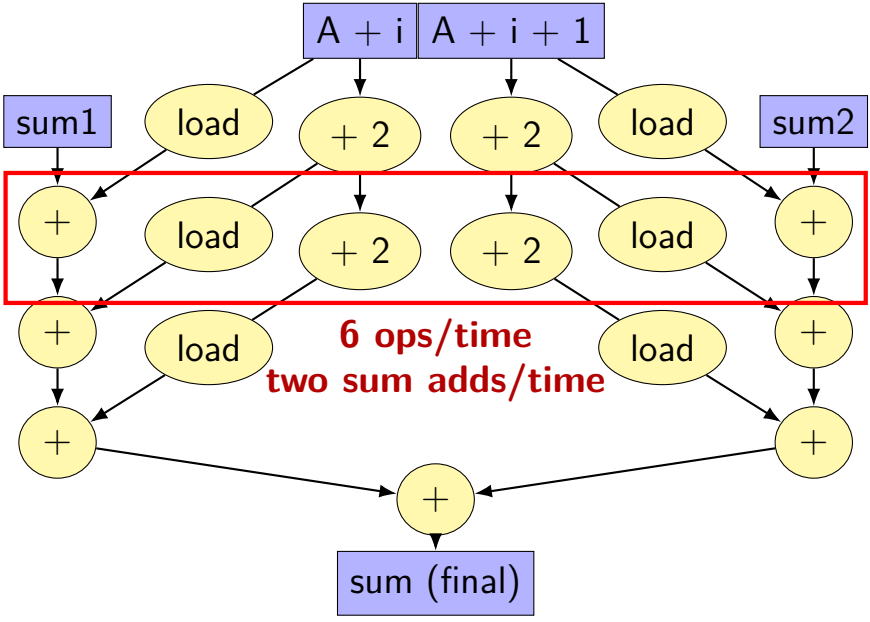


can only do sums one at a time

better data-flow



better data-flow



better data-flow
