things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

privileged operation: problem

how can hardware (HW) plus operating system (OS) allow:
 read your own files from hard drive

but disallow:
 read others files from hard drive

some ideas

OS tells HW 'okay' parts of hard drive before running program code

complex for hardware and for OS

some ideas

OS tells HW 'okay' parts of hard drive before running program code

- complex for hardware and for OS

OS verifies your program's code can't do bad hard drive access

- no work for HW, but complex for OS

- may require compiling differently to allow analysis

some ideas

OS tells HW 'okay' parts of hard drive before running program code

- complex for hardware and for OS

OS verifies your program's code can't do bad hard drive access

- no work for HW, but complex for OS

- may require compiling differently to allow analysis

OS tells HW to only allow OS-written code to access hard drive

- that code can enforce only 'good' accesses

- requires program code to call OS routines to access hard drive

- relatively simple for hardware

kernel mode

extra one-bit register: “are we in *kernel mode*”

other names: privileged mode, supervisor mode, ...

not in kernel mode = *user mode*

certain operations only allowed in kernel mode

privileged instructions

example: talking to any I/O device

what runs in kernel mode?

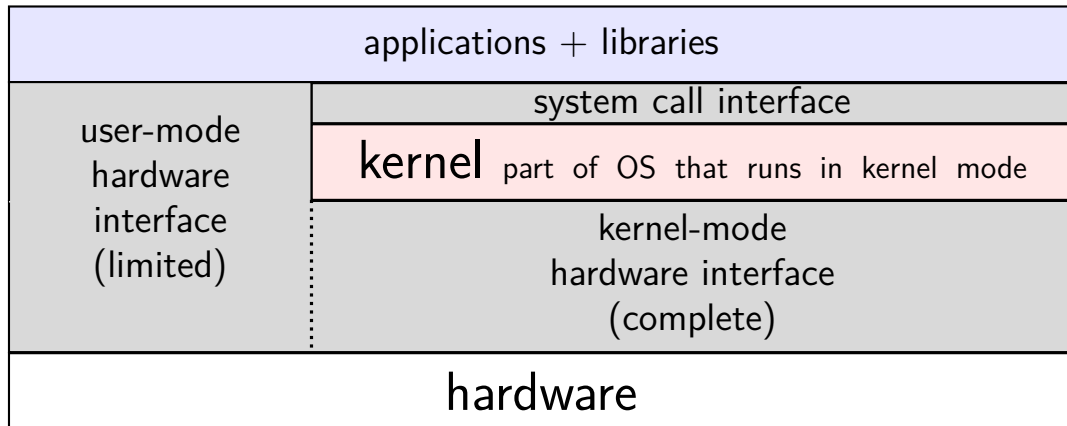

system boots in kernel mode

OS switches to user mode to run program code

next topic: when does system switch back to kernel mode?

how does OS tell HW where the (trusted) OS code is?

hardware + system call interface

calling the OS?

controlled entry to kernel mode (1)

special instruction: “system call”

runs OS code in kernel mode at location specified earlier

OS sets up at boot

location can't be changed without privileged instruction

controlled entry to kernel mode (2)

OS needs to make specified location:

figure out what operation the program wants

calling convention, similar to function arguments + return value

be “safe” — not allow the program to do ‘bad’ things

example: checks whether current program is allowed to read file before reading it

requires exceptional care — program can try weird things

Linux x86-64 system calls

special instruction: `syscall`

runs OS specified code in kernel mode

Linux syscall calling convention

before `syscall`:

`%rax` — system call number

`%rdi`, `%rsi`, `%rdx`, `%r10`, `%r8`, `%r9` — args

after `syscall`:

`%rax` — return value

on error: `%rax` contains -1 times “error number”

almost the same as normal function calls

Linux x86-64 hello world

```
.globl _start
.data
hello_str: .asciz "Hello, World!\n"
.text
_start:
    movq $1, %rax # 1 = "write"
    movq $1, %rdi # file descriptor 1 = stdout
    movq $hello_str, %rsi
    movq $15, %rdx # 15 = strlen("Hello, World!\n")
    syscall

    movq $60, %rax # 60 = exit
    movq $0, %rdi
    syscall
```

approx. system call handler

```
sys_call_table:  
    .quad handle_read_syscall  
    .quad handle_write_syscall  
    // ...  
  
handle_syscall:  
    ... // save old PC, etc.  
    pushq %rcx // save registers  
    pushq %rdi  
    ...  
    call *sys_call_table(,%rax,8)  
    ...  
    popq %rdi  
    popq %rcx  
    return_from_exception
```

Linux system call examples

`mmap`, `brk` — allocate memory

`fork` — create new process

`execve` — run a program in the current process

`_exit` — terminate a process

`open`, `read`, `write` — access files

`socket`, `accept`, `getpeername` — socket-related

system call wrappers

library functions to not write assembly:

open:

```
movq $2, %rax // 2 = sys_open
// 2 arguments happen to use same registers
syscall
// return value in %eax
cmp $0, %rax
jl has_error
ret
```

has_error:

```
neg %rax
movq %rax, errno
movq $-1, %rax
ret
```

system call wrappers

library functions to not write assembly:

open:

```
movq $2, %rax // 2 = sys_open
// 2 arguments happen to use same registers
syscall
// return value in %eax
cmp $0, %rax
jl has_error
ret
```

has_error:

```
neg %rax
movq %rax, errno
movq $-1, %rax
ret
```

system call wrapper: usage

```
/* unistd.h contains definitions of:  
    O_RDONLY (integer constant), open() */  
#include <unistd.h>  
int main(void) {  
    int file_descriptor;  
    file_descriptor = open("input.txt", O_RDONLY);  
    if (file_descriptor < 0) {  
        printf("error: %s\n", strerror(errno));  
        exit(1);  
    }  
    ...  
    result = read(file_descriptor, ...);  
    ...  
}
```

system call wrapper: usage

```
/* unistd.h contains definitions of:  
    O_RDONLY (integer constant), open() */  
#include <unistd.h>  
int main(void) {  
    int file_descriptor;  
    file_descriptor = open("input.txt", O_RDONLY);  
    if (file_descriptor < 0) {  
        printf("error: %s\n", strerror(errno));  
        exit(1);  
    }  
    ...  
    result = read(file_descriptor, ...);  
    ...  
}
```

strace hello_world (1)

strace — Linux tool to trace system calls

run on assembly program we saw earlier:

```
$ strace -o trace.txt ./hello_world
```

```
$ cat trace.txt
```

```
execve("./hello_world", ["./hello_world"],  
          0x7ffeedafdf0a0 /* 28 vars */) = 0  
write(1, "Hello, World!\n\0", 14)      = 14  
exit(0)                                = ?  
+++ exited with 0 +++
```

strace hello_world (2)

```
#include <stdio.h>
int main() { puts("Hello, World!"); }
```

when statically linked:

```
execve("./hello_world", ["./hello_world"], 0x7ffeb4127f70 /* 28 vars */)
    = 0
brk(NULL)
    = 0x22f8000
brk(0x22f91c0)
    = 0x22f91c0
arch_prctl(ARCH_SET_FS, 0x22f8880)
    = 0
uname({sysname="Linux", nodename="reiss-t3620", ...}) = 0
readlink("/proc/self/exe", "/u/cr4bd/spring2023/cs3130/slide"..., 4096)
    = 57
brk(0x231a1c0)
    = 0x231a1c0
brk(0x231b000)
    = 0x231b000
access("/etc/ld.so.nohwcap", F_OK)
    = -1 ENOENT (No such file or
                                directory)
fstat(1, {st_mode=S_IFCHR|0620, st_rdev=makedev(136, 4), ...}) = 0
write(1, "Hello, World!\n", 14)
    = 14
exit_group(0)
    = ?
+++ exited with 0 +++
```

aside: what are those syscalls?

execve: run program

brk: allocate heap space

arch_prctl(ARCH_SET_FS, ...): thread local storage pointer
may make more sense when we cover concurrency/parallelism later

uname: get system information

readlink of /proc/self/exe: get name of this program

access: can we access this file [in this case, a config file]?

fstat: get information about open file

exit_group: variant of exit

strace hello_world (2)

```
#include <stdio.h>
int main() { puts("Hello, World!"); }
```

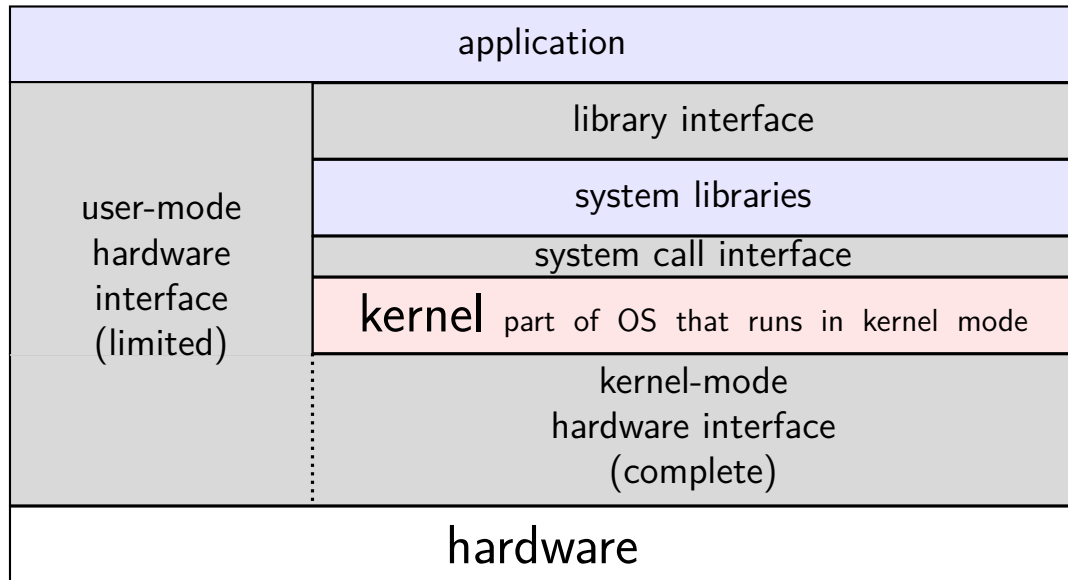

when dynamically linked:

```
execve("./hello_world", ["./hello_world"], 0x7ffcfe91d540 /* 28 vars */)
    = 0
brk(NULL)
    = 0x55d6c351b000
...
openat(AT_FDCWD, "/etc/ld.so.cache", O_RDONLY|O_CLOEXEC) = 3
fstat(3, {st_mode=S_IFREG|0644, st_size=196684, ...}) = 0
mmap(NULL, 196684, PROT_READ, MAP_PRIVATE, 3, 0) = 0x7f7a62dd3000
close(3)
    = 0
access("/etc/ld.so.nohwcap", F_OK)
    = -1 ENOENT (No such file or directory)
openat(AT_FDCWD, "/lib/x86_64-linux-gnu/libc.so.6", O_RDONLY|O_CLOEXEC) = 3
read(3, "\177ELF\2\1\1\3\0\0\0\0\0\0\0\0\0\3\0>\0\1\0\0\0"..., 832) = 832
...
close(3)
    = 0
write(1, "Hello, World!\n", 14)
    = 14
exit_group(0)
    = ?
+++ exited with 0 +++
```

hardware + system call interface

hardware + system call + library interface

things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

memory protection

modifying another program's memory?

Program A	Program B
<pre>0x10000: .long 42 // ... // do work // ... movq 0x10000, %rax</pre>	<pre><i>// while A is working:</i> movq \$99, %rax movq %rax, 0x10000 ...</pre>

memory protection

modifying another program's memory?

Program A	Program B
<pre>0x10000: .long 42 // ... // do work // ... movq 0x10000, %rax</pre>	<pre><i>// while A is working:</i> movq \$99, %rax movq %rax, 0x10000 ...</pre>
<p>result: %rax (in A) is ...</p> <p>A. 42 B. 99 C. 0x10000</p> <p>D. 42 or 99 (depending on timing/program layout/etc)</p> <p>E. 42 or 99 or program might crash (depending on ...)</p> <p>F. something else</p>	

program memory (two programs)

Program A

Program B

address space

programs have **illusion of own memory**

called a program's **address space**

program memory (two programs)

Program A

Program B

address space

programs have **illusion of own memory**

called a program's **address space**

address space mechanisms

topic after exceptions

called **virtual memory**

mapping called **page tables**

mapping part of what is changed in context switch

shared memory

recall: dynamically linked libraries

would be nice not to duplicate code/data...

we can!

one way to set shared memory on Linux

```
/* regular file, OR: */  
int fd = open("/tmp/somefile.dat", O_RDWR);  
/* special in-memory file */  
int fd = shm_open("/name", O_RDWR);  
...  
/* make file's data accessible as memory */  
void *memory = mmap(NULL, size, PROT_READ | PROT_WRITE,  
                    MAP_SHARED, fd, 0);
```

mmap: “map” a file’s data into your memory

will discuss a bit more when we talk about virtual memory

part of how Linux loads dynamically linked libraries

memory protection

modifying another program's memory?

Program A	Program B
<pre>0x10000: .long 42 // ... // do work // ... movq 0x10000, %rax</pre>	<pre><i>// while A is working:</i> movq \$99, %rax movq %rax, 0x10000 ...</pre>
result: %rax (in A) is 42 (always) A. 42 B. 99 C. 0x10000 D. 42 or 99 (depending on timing/program layout/etc) E. 42 or 99 or program might crash (depending on ...) F. something else	result: might crash

program crashing?

what happens on processor when program crashes?

other program informed of crash to display message

use processor to run some other program

program crashing?

what happens on processor when program crashes?

other program informed of crash to display message

use processor to run some other program

how does hardware do this?

would be complicated to tell about other programs, etc.

instead: hardware runs designated OS routine

exceptions

recall: system calls — software asks OS for help

also cases where hardware asks OS for help

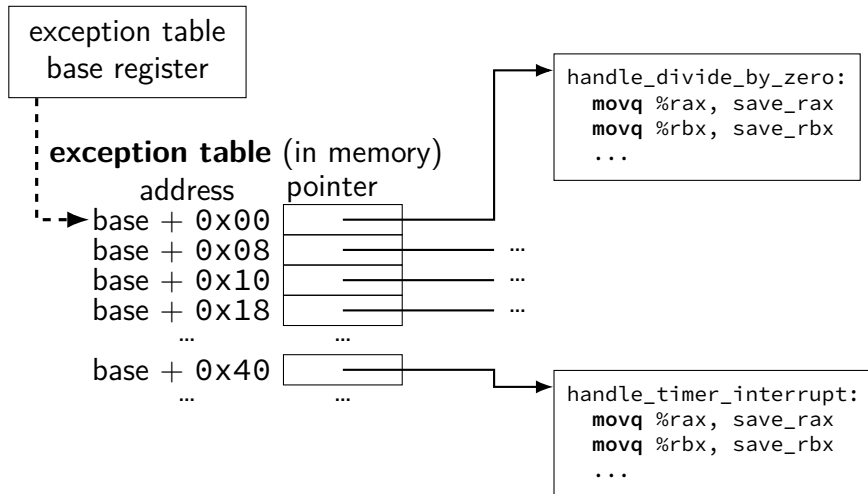

different triggers than system calls

but same mechanism as system calls:

- switch to kernel mode (if not already)

- call OS-designated function

locating exception handlers (one strategy)

types of exceptions

- system calls

 - intentional — ask OS to do something

- errors/events in programs

 - memory not in address space (“Segmentation fault”)

 - privileged instruction

 - divide by zero, invalid instruction

 - ...

- (and more we'll talk about later)

types of exceptions

system calls

intentional — ask OS to do something

errors/events in programs

memory not in address space (“Segmentation fault”)

privileged instruction

divide by zero, invalid instruction

...

(and more we'll talk about later)

types of exceptions

- system calls

 - intentional — ask OS to do something

- errors/events in programs

 - memory not in address space (“Segmentation fault”)

 - privileged instruction

 - divide by zero, invalid instruction

 - ...

- (and more we'll talk about later)

types of exceptions

system calls

intentional — ask OS to do something

errors/events in programs

memory not in address space (“Segmentation fault”)

privileged instruction

divide by zero, invalid instruction

...

(and more we'll talk about later)

synchronous

triggered by
current program

things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

an infinite loop

```
int main(void) {  
    while (1) {  
        /* waste CPU time */  
    }  
}
```

If I run this on a shared department machine, can you still use it?
...if the machine only has one core?

timing nothing

```
long times[NUM_TIMINGS];  
int main(void) {  
    for (int i = 0; i < N; ++i) {  
        long start, end;  
        start = get_time();  
        /* do nothing */  
        end = get_time();  
        times[i] = end - start;  
    }  
    output_timings(times);  
}
```

same instructions — same difference each time?

doing nothing on a busy system

doing nothing on a busy system

types of exceptions

system calls

intentional — ask OS to do something

errors/events in programs

memory not in address space (“Segmentation fault”)

privileged instruction

divide by zero, invalid instruction

...

synchronous

triggered by
current program

external — I/O, etc.

timer — configured by OS to run OS at certain time

I/O devices — key presses, hard drives, networks, ...

hardware is broken (e.g. memory parity error)

asynchronous

not triggered by
running program

time multiplexing

processor:

time multiplexing

...

```
call get_time
```

```
// whatever get_time does
```

```
movq %rax, %rbp
```

———— million cycle delay ————

```
call get_time
```

```
// whatever get_time does
```

```
subq %rbp, %rax
```

...

time multiplexing

...

```
call get_time
```

```
// whatever get_time does
```

```
movq %rax, %rbp
```

———— million cycle delay ————

```
call get_time
```

```
// whatever get_time does
```

```
subq %rbp, %rax
```

...

time multiplexing really

 = operating system

time multiplexing really

= operating system

exception happens

return from exception

types of exceptions

system calls

intentional — ask OS to do something

errors/events in programs

memory not in address space (“Segmentation fault”)

privileged instruction

divide by zero, invalid instruction

...

synchronous

triggered by
current program

external — I/O, etc.

timer — configured by OS to run OS at certain time

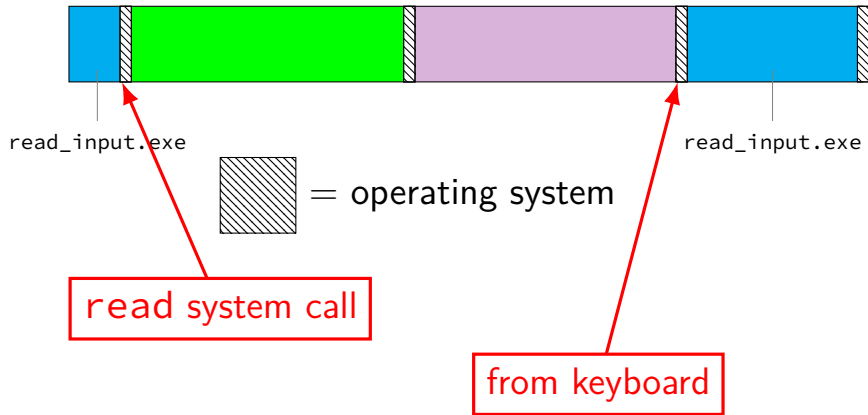

I/O devices — key presses, hard drives, networks, ...

hardware is broken (e.g. memory parity error)

asynchronous

not triggered by
running program

keyboard input timeline

crash timeline timeline

segfault.exe

= operating system

out of bounds memory access

threads

thread = illusion of own processor

own register values

own program counter value

threads

thread = illusion of own processor

own register values

own program counter value

actual implementation:

many threads sharing one processor

problem: where are register/program counter values
when thread not active on processor?

switching programs

OS starts running somehow
some sort of exception

saves old registers + program counter
(optimization: could omit when program crashing/exiting)

sets new registers, jumps to new program counter

called **context switch**
saved information called **context**

contexts (A running)

contexts (B running)

review: definitions

exception: hardware calls OS specified routine

- many possible reasons

- system calls: type of exception

context switch: OS switches to another thread

- by saving old register values + loading new ones

- part of OS routine run by exception

which of these require exceptions? context switches?

- A. program calls a function in the standard library
- B. program writes a file to disk
- C. program A goes to sleep, letting program B run
- D. program exits
- E. program returns from one function to another function
- F. program pops a value from the stack

terms for exceptions

terms for exceptions aren't standardized

our readings use one set of terms

- interrupts = externally-triggered

- faults = error/event in program

- trap = intentionally triggered

all these terms appear differently elsewhere

The Process

process = thread(s) + address space

illusion of **dedicated machine**:

thread = illusion of own CPU

address space = illusion of own memory
