last time

anonymous feedback (1)

"I think you cut off people during their questions too much. It would be nice if students could finish their questions and get them answered correctly."

anonymous feedback (2)

"I'm not sure if this applies to every single lab but at least for mine (330-445) the lab room feels insanely crowded. There often aren't enough chairs for everyone and one of the TAs told me that a lot of people just dont leave after their lab and stay for 2 or more lab sessions...I'm not really sure how this could be solved I just thought it was worth pointing out because the effect sort of compounds into later lab sessions since people who have a late lab and aren't able to finish in lab dont have as much time to work on it after lab class."

aside on sudo

should have explained what sudo is

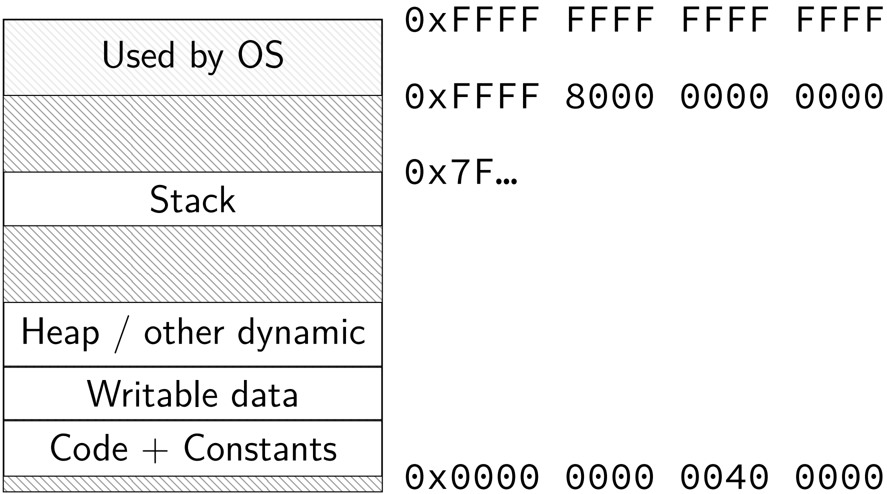
utility system admin configures to allow some people to run things with extra permissions

usually prompts for password first

trick: because set-user-ID program, program with if statements

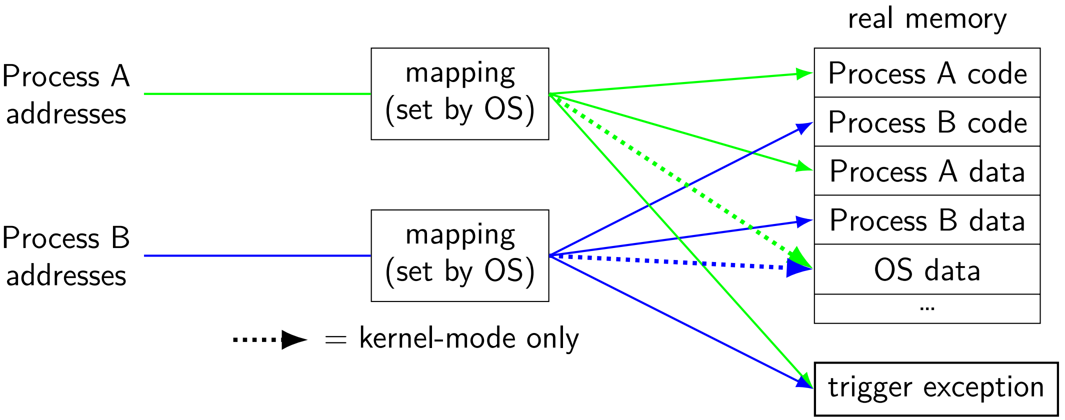
kernel “delegates” decision to the program

program memory



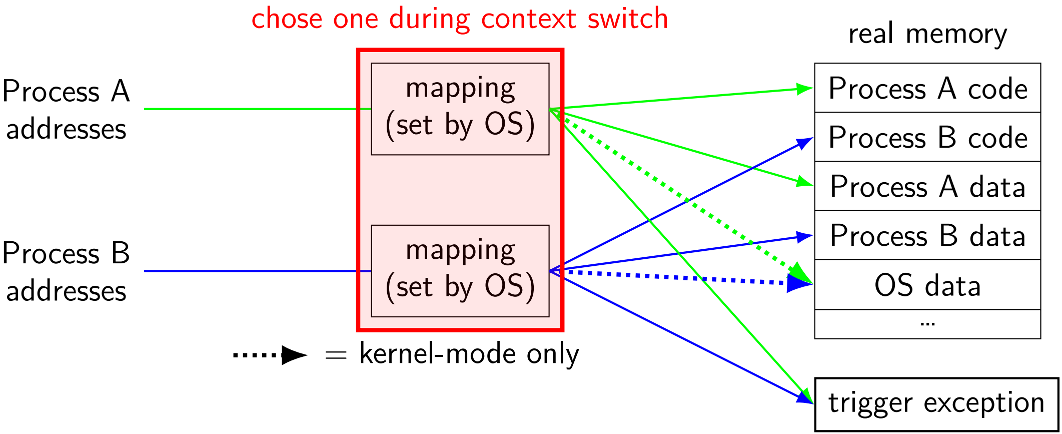
address spaces

illuision of dedicated memory



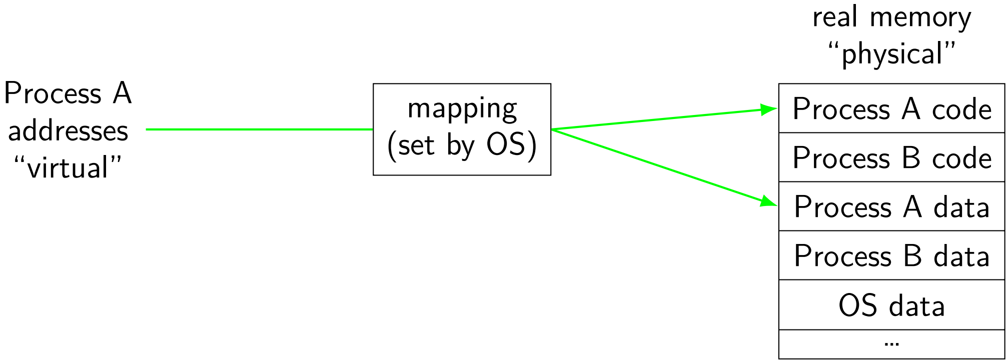
address spaces

illuision of dedicated memory

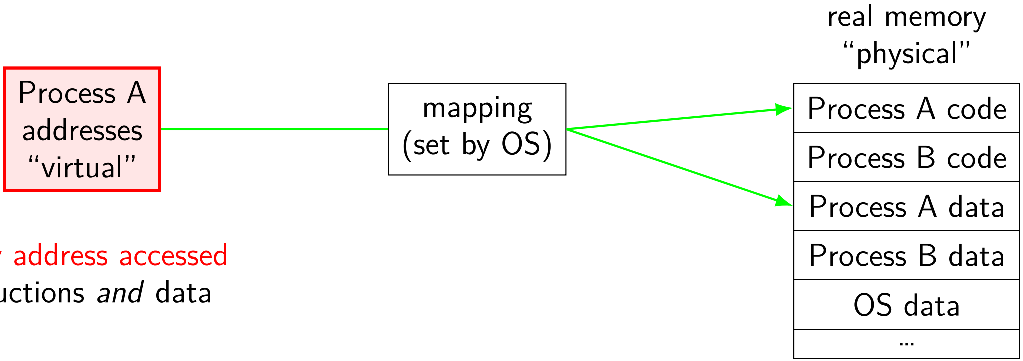


= kernel-mode only

address translation

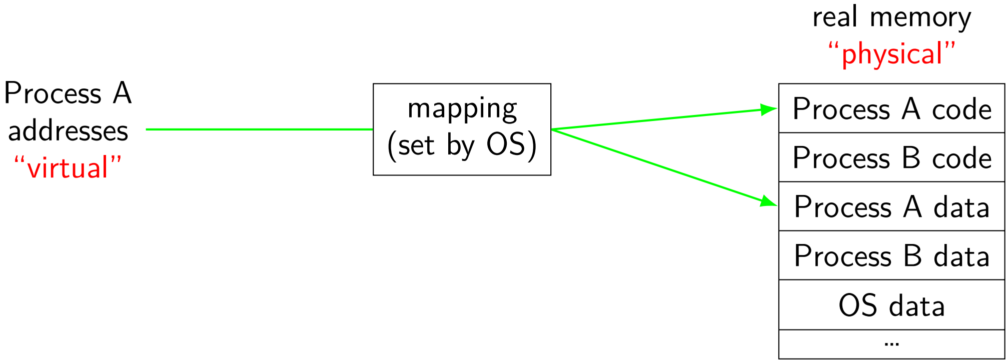


address translation



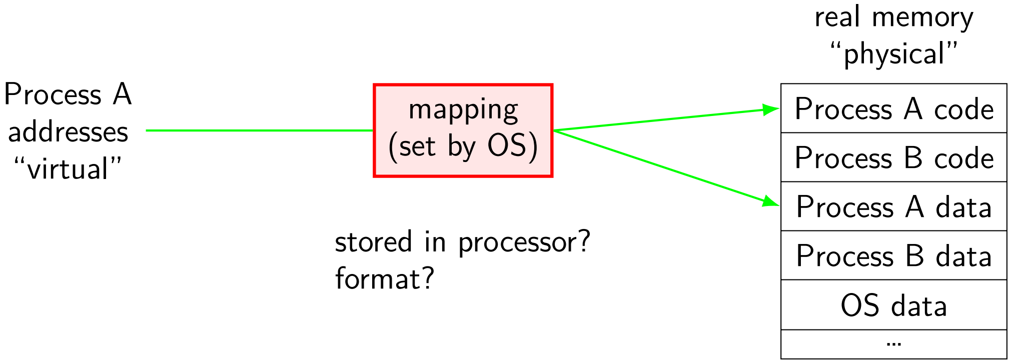
every address accessed
instructions *and* data

address translation



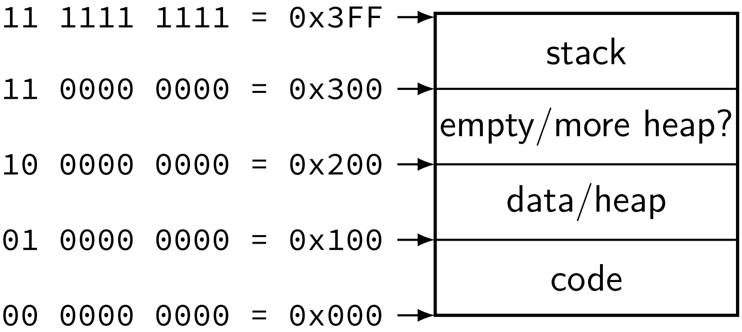
program addresses are 'virtual'
real addresses are 'physical'
can be different sizes!

address translation

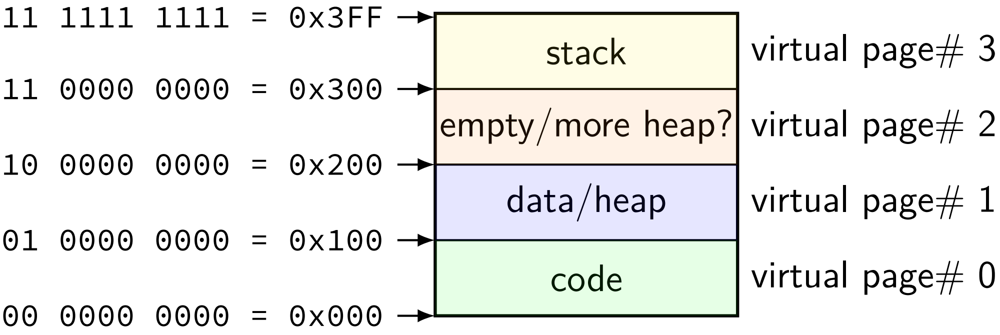


stored in processor?
format?

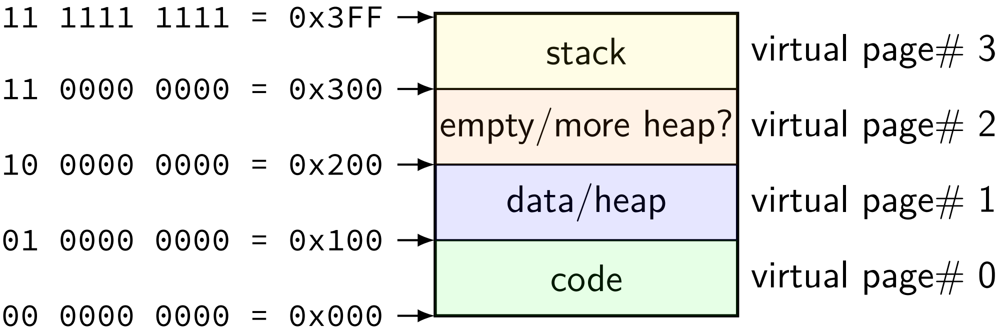
toy program memory



toy program memory

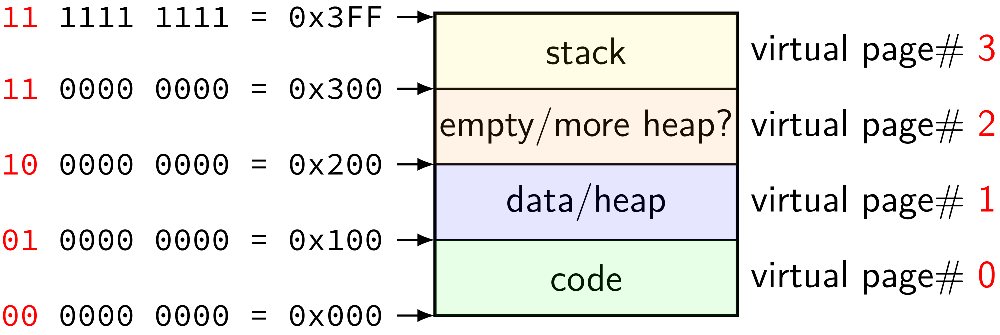


toy program memory



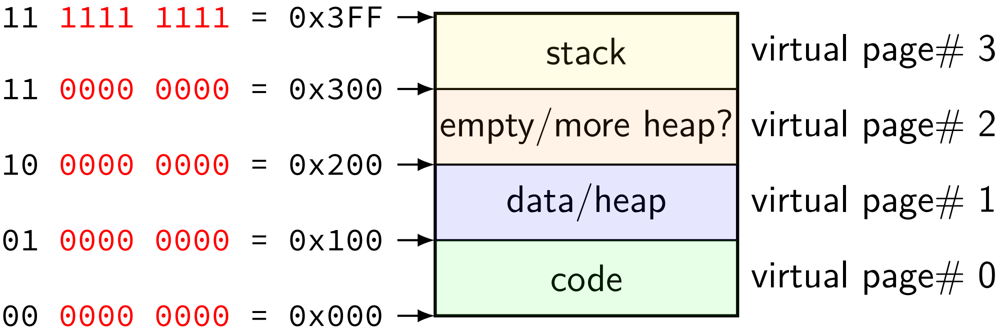
divide memory into pages (2^8 bytes in this case)
"virtual" = addresses the program sees

toy program memory



page number is upper bits of address
(because page size is power of two)

toy program memory



rest of address is called page offset

toy physical memory

program memory
virtual addresses

`11 0000 0000 to 11 1111 1111`
`10 0000 0000 to 10 1111 1111`
`01 0000 0000 to 01 1111 1111`
`00 0000 0000 to 00 1111 1111`

real memory
physical addresses

`111 0000 0000 to 111 1111 1111`
`001 0000 0000 to 001 1111 1111`
`000 0000 0000 to 000 1111 1111`

toy physical memory

program memory

virtual addresses

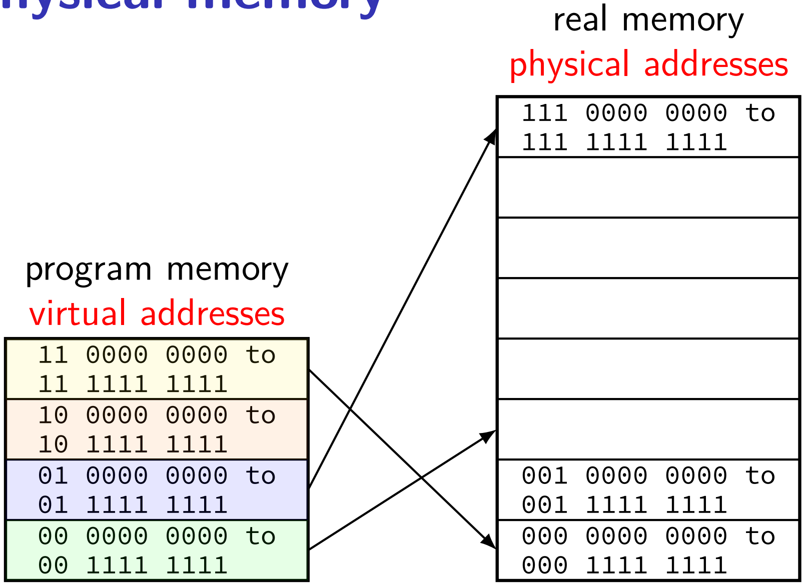
11 0000 0000 to 11 1111 1111
10 0000 0000 to 10 1111 1111
01 0000 0000 to 01 1111 1111
00 0000 0000 to 00 1111 1111

real memory

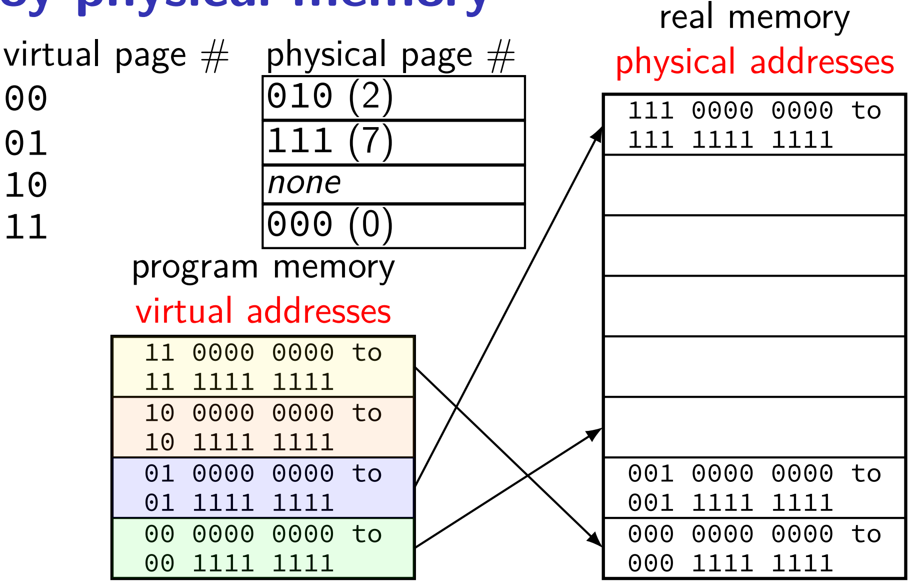
physical addresses

111 0000 0000 to 111 1111 1111	physical page 7
001 0000 0000 to 001 1111 1111	physical page 1
000 0000 0000 to 000 1111 1111	physical page 0

toy physical memory



toy physical memory



toy physical memory

virtual page #	physical page #
00	010 (2)
01	111 (7)
10	*none*
11	000 (0)

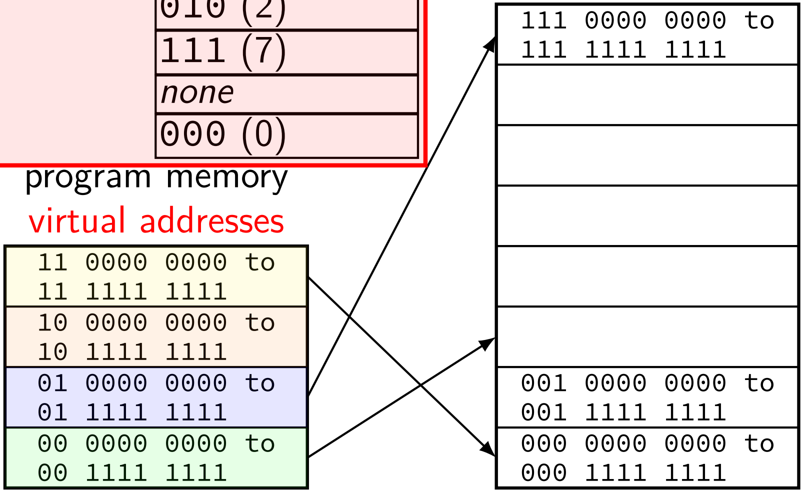
page table!

program memory

virtual addresses

real memory

physical addresses



toy page table lookup

virtual page #	valid?	physical page #
`00`	`1`	`010` (2, code)
`01`	`1`	`111` (7, data)
`10`	`0`	`???` (ignored)
`11`	`1`	`000` (0, stack)

switching page tables

part of context switch is changing the page table

extra privileged instructions

switching page tables

part of context switch is changing the page table

extra privileged instructions

where in memory is the code that does this switching?

switching page tables

part of context switch is changing the page table

extra privileged instructions

where in memory is the code that does this switching?

- probably have a page table entry pointing to it
- hopefully marked kernel-mode-only

switching page tables

part of context switch is changing the page table

extra privileged instructions

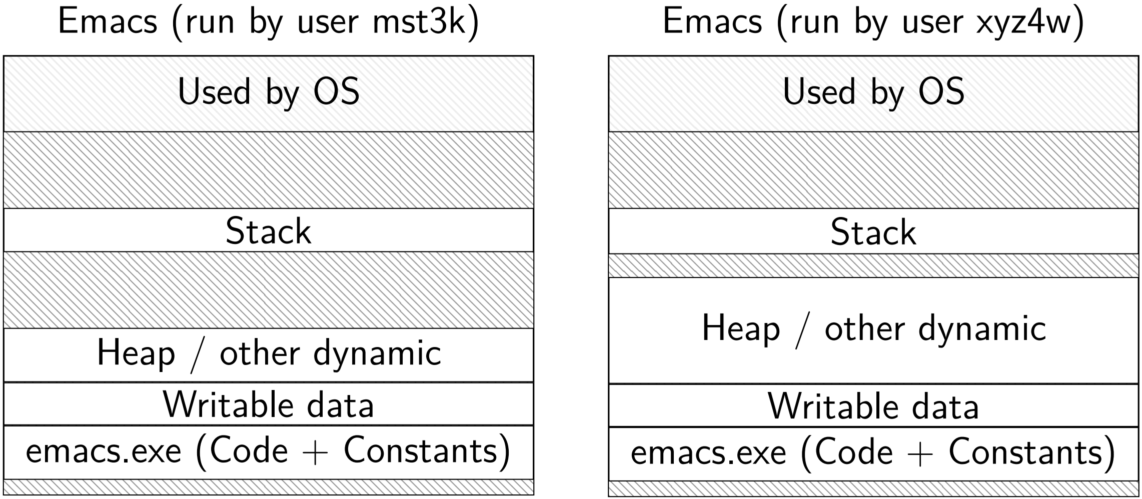
where in memory is the code that does this switching?

- probably have a page table entry pointing to it
- hopefully marked kernel-mode-only

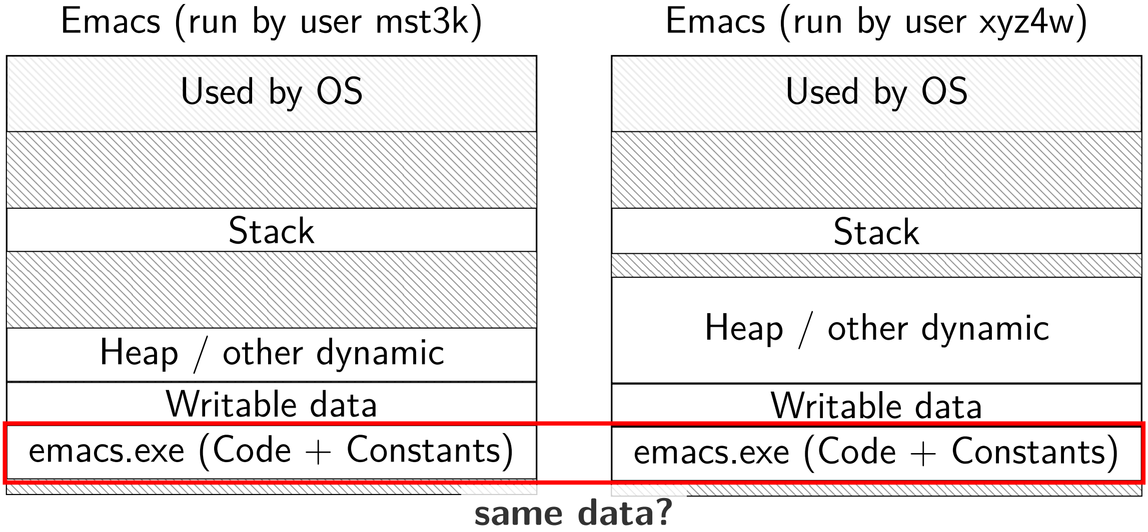
code better not be modified by user program

- otherwise: uncontrolled way to “escape” user mode

emacs (two copies)



emacs (two copies)



two copies of program

would like to only have one copy of program

what if `mst3k`'s emacs tries to modify its code?

would break process abstraction:

  "illusion of own memory"

typical page table entries

solution: same idea as kernel-only bit

page table entry will have more permissions bits

- can read?
- can write?
- can execute?

checked by MMU like valid/kernel bit

page table (logically)

virtual page #	valid?	kernel?	write?	exec?	physical page #
0000 0000	0	0	0	0	00 0000 0000
0000 0001	1	0	1	0	10 0010 0110
0000 0010	1	0	1	0	00 0000 1100
0000 0011	1	0	0	1	11 0000 0011
…					
1111 1111	1	0	1	0	00 1110 1000

on virtual address sizes

virtual address size = size of pointer?

often, but — sometimes part of pointer not used

example: typical x86-64 only use 48 bits

- rest of bits have fixed value

virtual address size is amount used for mapping

address space sizes

amount of stuff that can be addressed $=$ address space size

based on number of unique addresses

e.g. 32-bit virtual address $= 2^{32}$ byte virtual address space

e.g. 20-bit physical addresss $= 2^{20}$ byte physical address space

address space sizes

amount of stuff that can be addressed $=$ address space size

- based on number of unique addresses

e.g. 32-bit virtual address $= 2^{32}$ byte virtual address space

e.g. 20-bit physical addresss $= 2^{20}$ byte physical address space

what if my machine has 3GB of memory (not power of two)?

- not all addresses in physical address space are useful
- most common situation (since CPUs support having a lot of memory)

exercise: page counting

suppose 32-bit virtual (program) addresses

and each page is 4096 bytes (2^{12} bytes)

how many virtual pages?

exercise: page counting

suppose 32-bit virtual (program) addresses

and each page is 4096 bytes (2^{12} bytes)

how many virtual pages?

exercise: page table size

suppose 32-bit virtual (program) addresses

suppose 30-bit physical (hardware) addresses

each page is 4096 bytes (2^{12} bytes)

pgae table entries have physical page $\#$, valid bit, kernel-mode bit

how big is the page table (if laid out like ones we've seen)?

exercise: page table size

suppose 32-bit virtual (program) addresses

suppose 30-bit physical (hardware) addresses

each page is 4096 bytes (2^{12} bytes)

pgae table entries have physical page $\#$, valid bit, kernel-mode bit

how big is the page table (if laid out like ones we've seen)?

- issue: where can we store that?

exercise: address splitting

and each page is 4096 bytes (2^{12} bytes)

split the address `0x12345678` into page number and page offset:

exercise: address splitting

and each page is 4096 bytes (2^{12} bytes)

split the address `0x12345678` into page number and page offset:

4096 byte pages

exercise: how many page table entries? (assuming page table like shown before)

exercise: how large are physical page numbers?

exercise: 64-bit system

my desktop: 39-bit physical addresses; 48-bit virtual addresses

4096 byte pages

exercise: how many page table entries? (assuming page table like shown before)

exercise: how large are physical page numbers?

page table entries are 8 bytes (room for expansion, metadata)

- trick: power of two size makes table lookup faster

would take up 2^{39} bytes?? (512GB??)

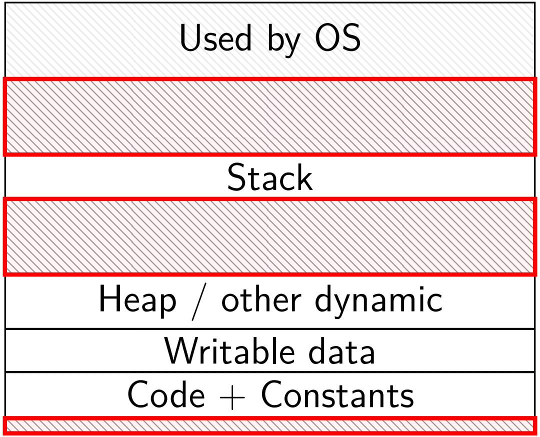
huge page tables

huge virtual address spaces!

impossible to store PTE for every page

how can we save space?

holes



most pages are invalid

saving space

basic idea: don't store (most) invalid page table entries

use a data structure other than a flat array

- want a map — lookup key (virtual page number), get value (PTE)

options?

saving space

basic idea: don't store (most) invalid page table entries

use a data structure other than a flat array

- want a map — lookup key (virtual page number), get value (PTE)

options?

hashtable

- actually used by some historical processors
- but never common

saving space

basic idea: don't store (most) invalid page table entries

use a data structure other than a flat array

- want a map — lookup key (virtual page number), get value (PTE)

options?

hashtable

- actually used by some historical processors
- but never common

tree data structure

- but not quite a search tree

search tree tradeoffs

lookup usually implemented in hardware

- lookup should be simple
- solution: lookup splits up address bits (no complex calculations)

lookup should not involve many memory accesses

- doing two memory accesses is already very slow
- solution: tree with many children from each node
  - (far from binary tree's left/right child)

two-level page table lookup

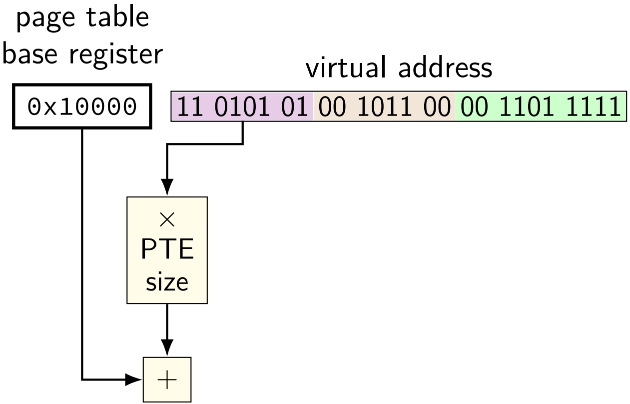
virtual address

11 0101 01	00 1011 00	00 1101 1111

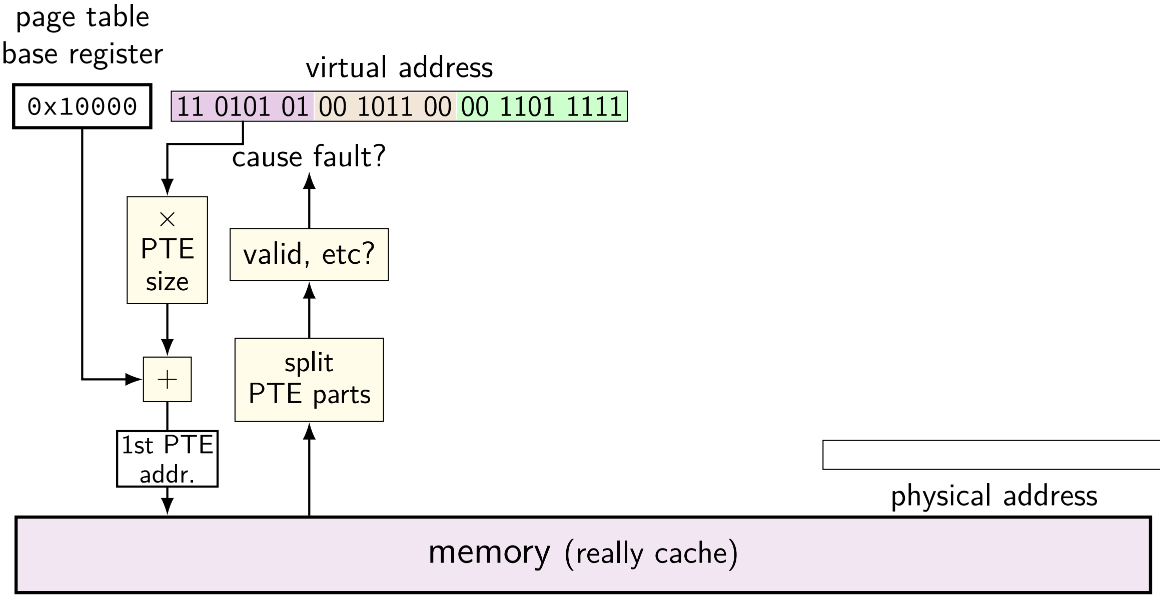
VPN — split into two parts (one per level)

this example: parts equal sized — common, but not required

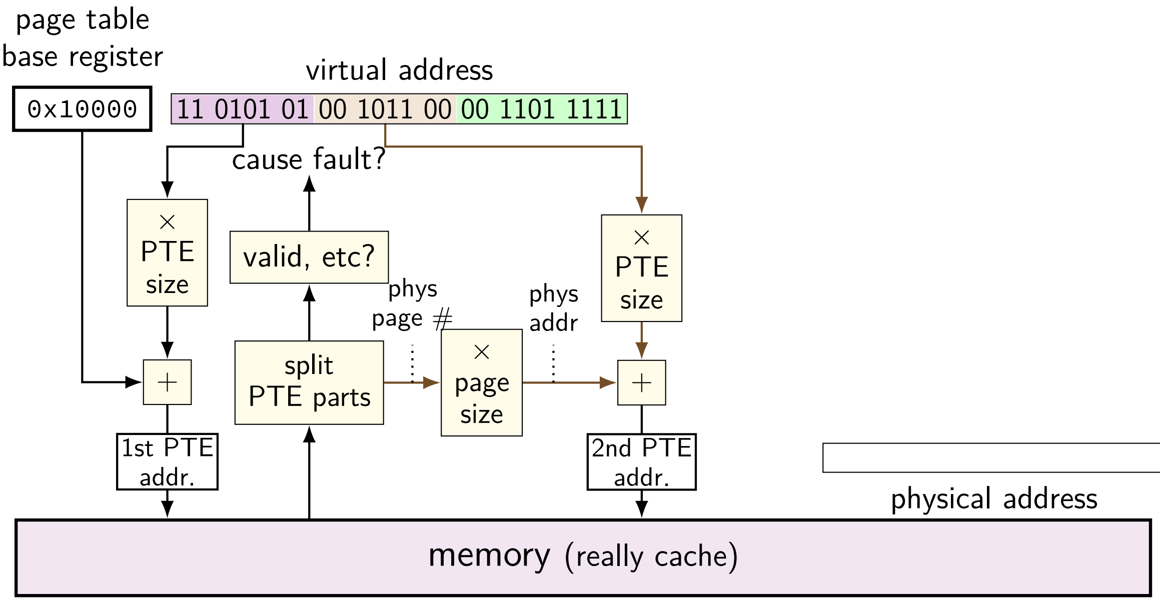
two-level page table lookup



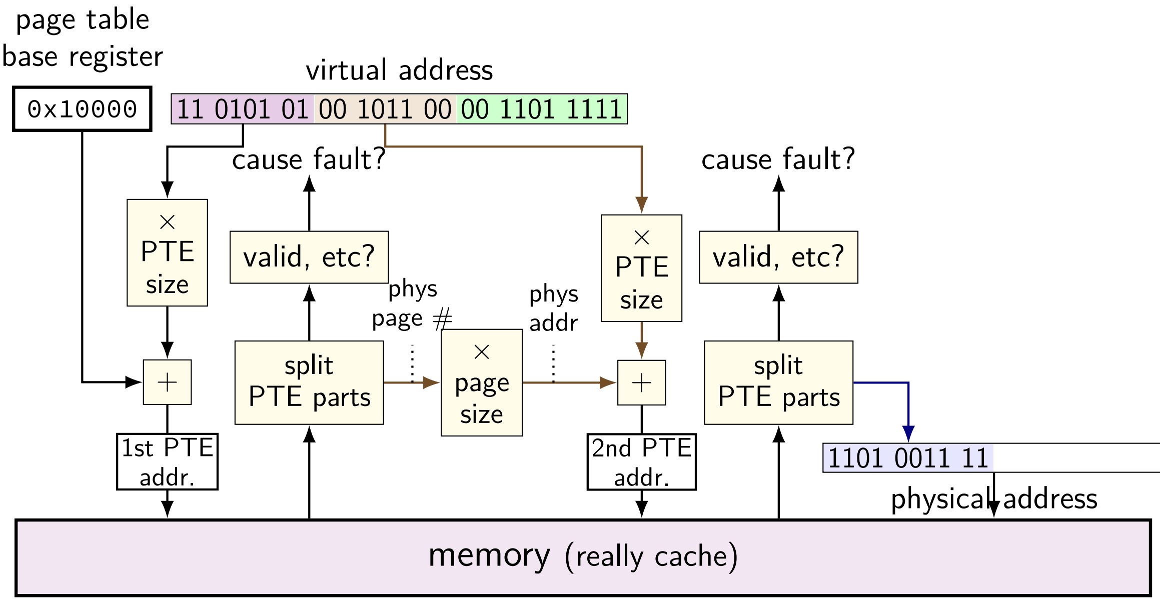
two-level page table lookup



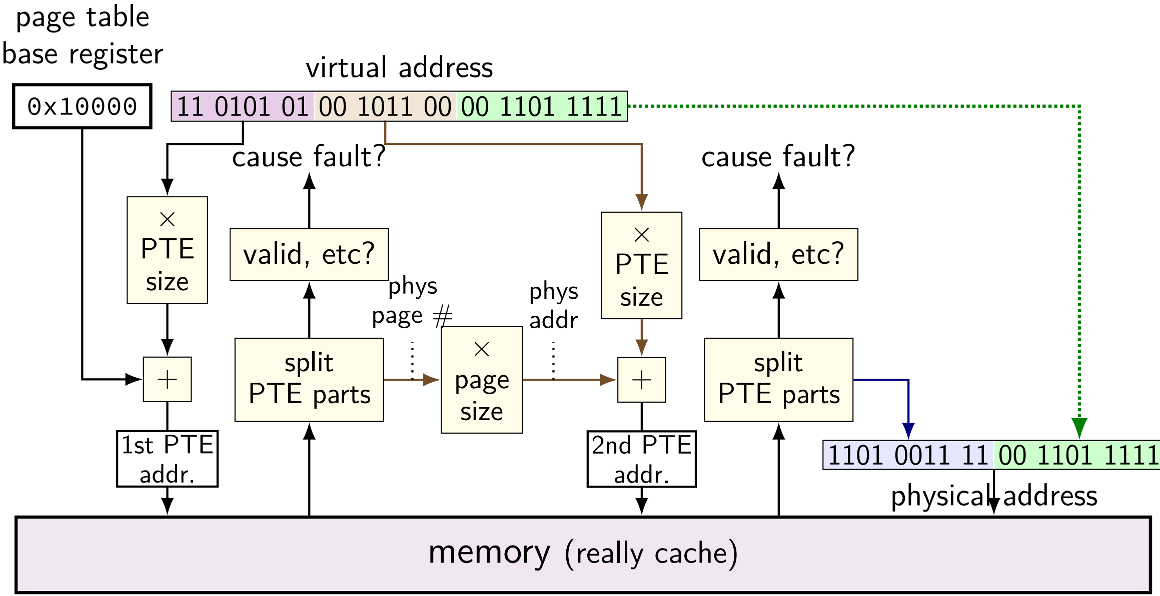
two-level page table lookup



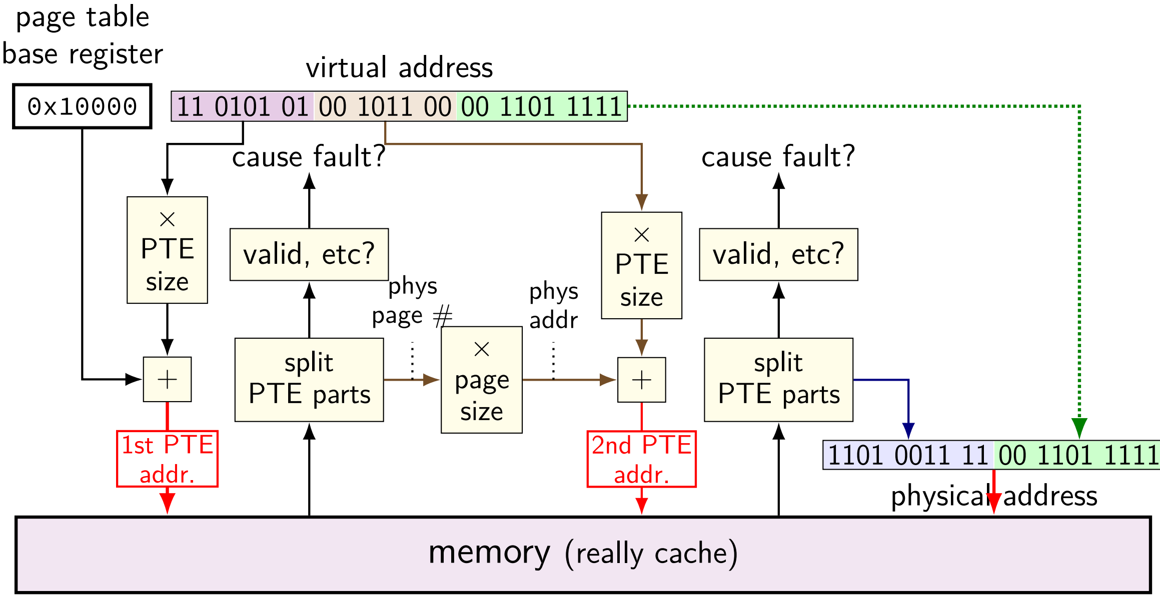
two-level page table lookup



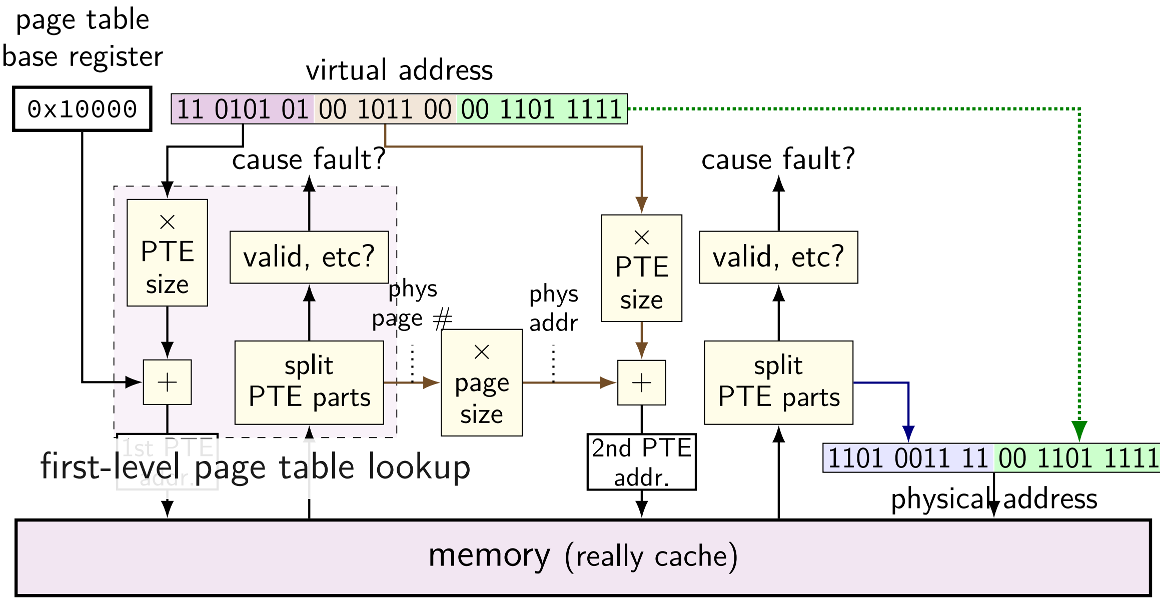
two-level page table lookup



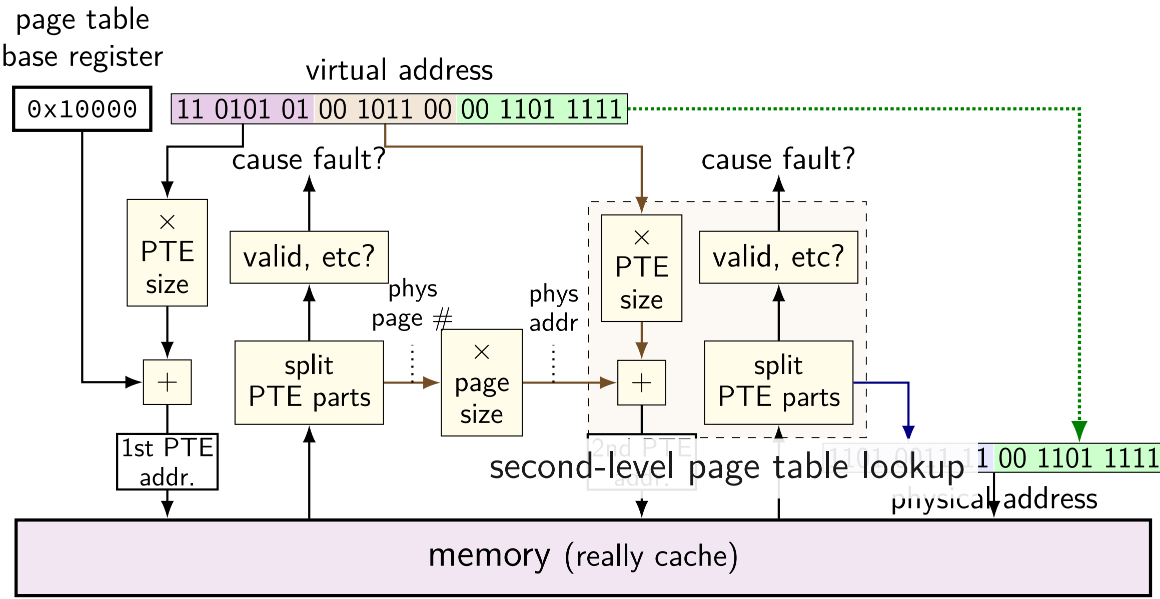
two-level page table lookup



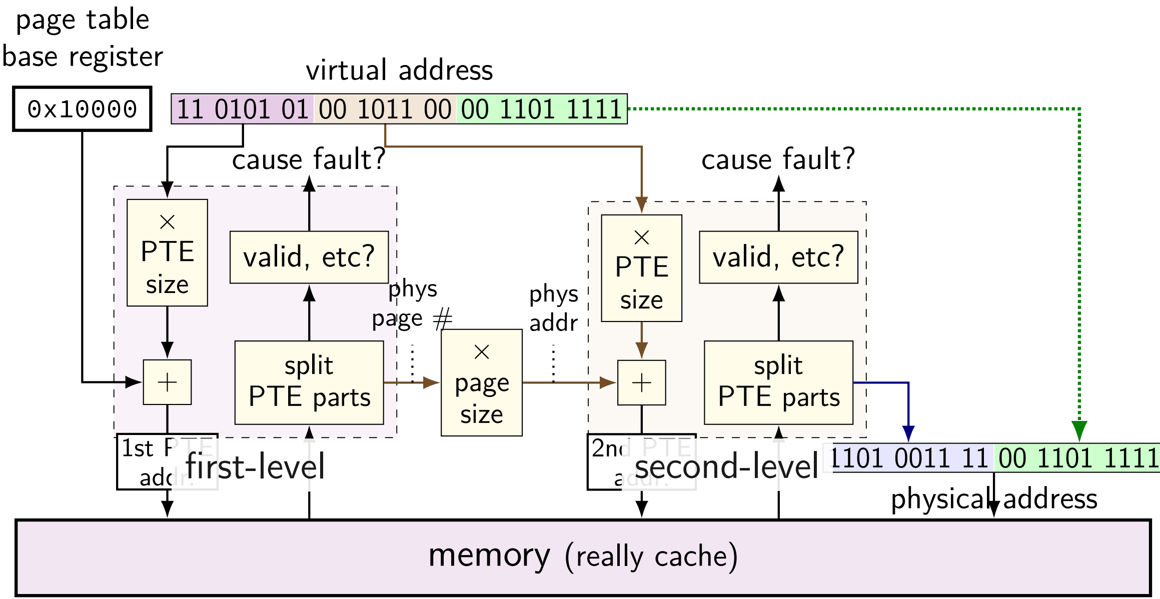
two-level page table lookup



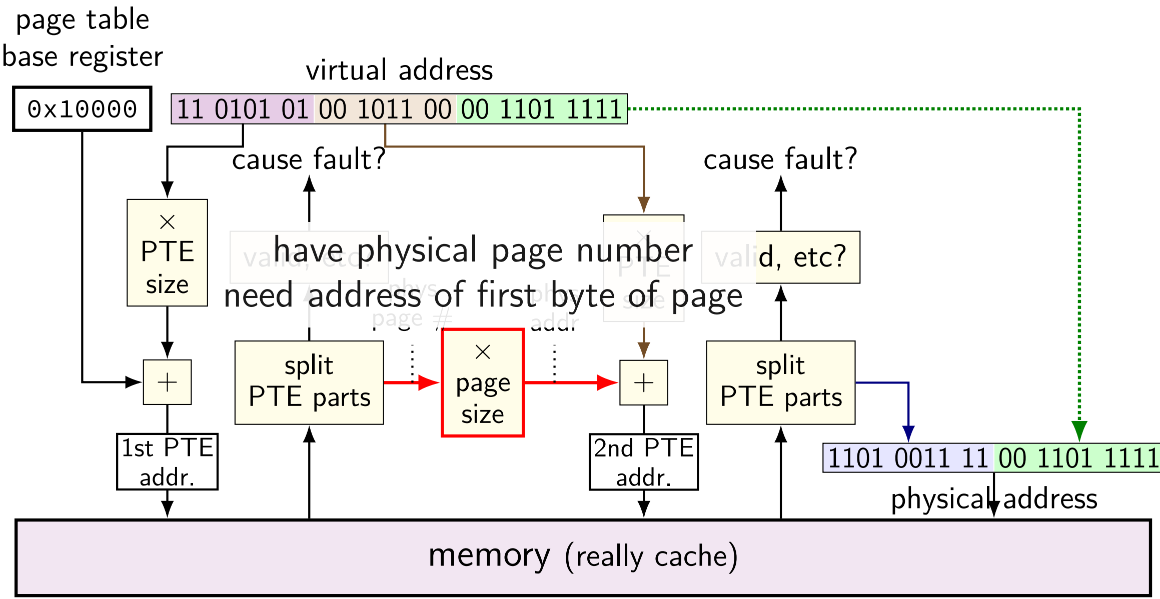
two-level page table lookup



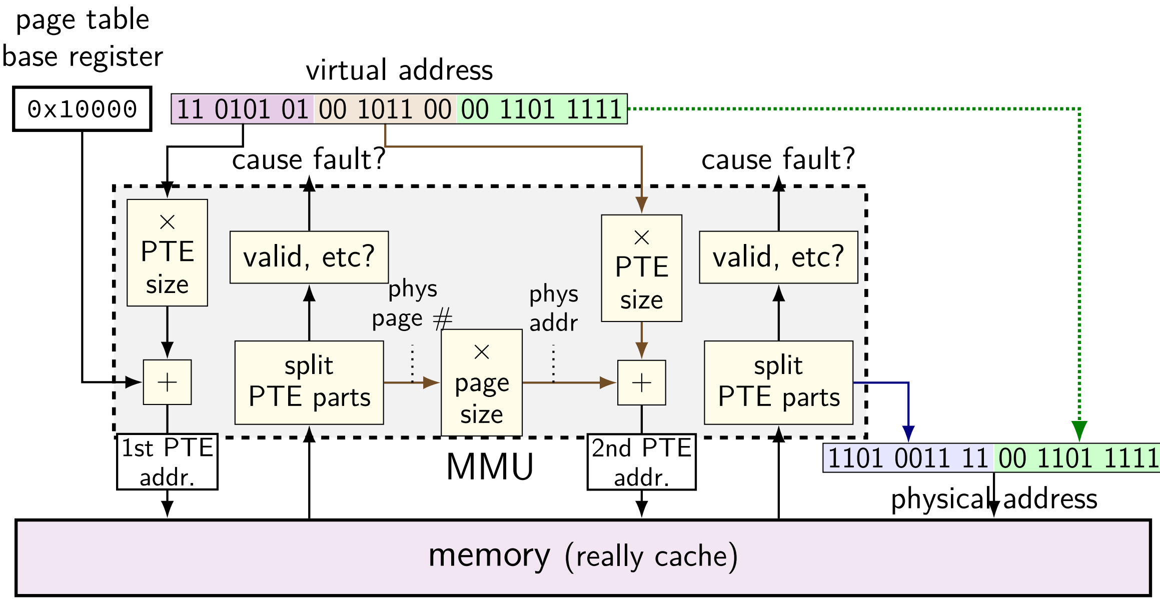
two-level page table lookup



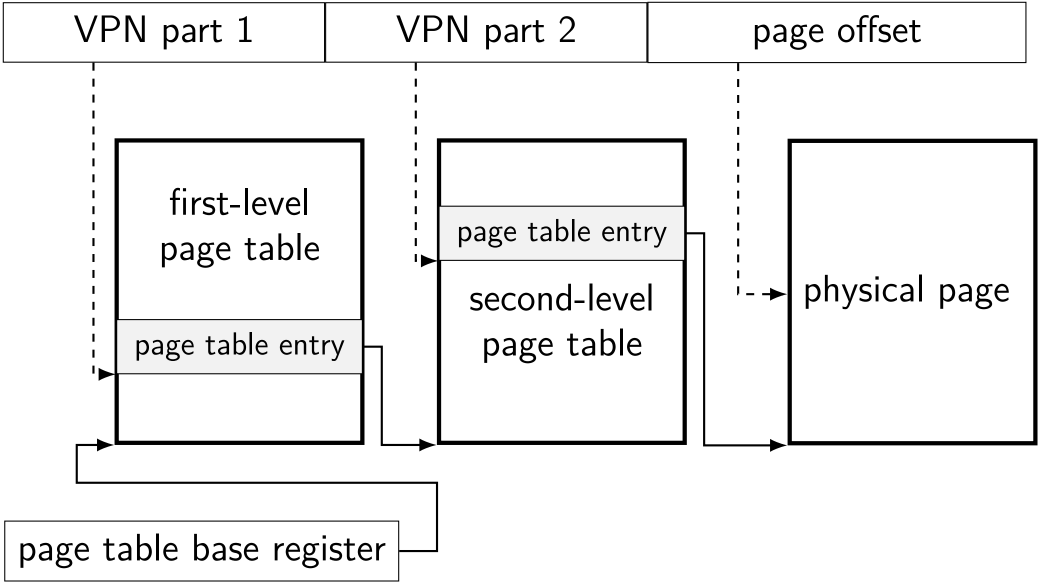
two-level page table lookup



two-level page table lookup



another view



multi-level page tables

VPN split into pieces for each level of page table

top levels: page table entries point to next page table

usually using physical page number of next page table

bottom level: page table entry points to destination page

validity and permission checks at each level

x86-64 page table splitting

48-bit virtual address

12-bit page offset (4KB pages)

36-bit virtual page number, split into four 9-bit parts

page tables at each level: 2^9 entries, 8 bytes/entry

- deliberate choice: each page table is one page

note on VPN splitting

textbook labels it ‘VPN 1’ and ‘VPN 2’ and so on

these are parts of the virtual page number

(there are not multiple VPNs)

2-level example

9-bit virtual addresses, 6-bit physical; 8 byte pages, 1 byte PTE

page tables 1 page; PTE: 3 bit PPN (MSB), 1 valid bit, 4 unused

page table base register `0x20`; translate virtual address `0x131`

…	…	…

in exception handler, OS allocates more stack space
OS updates the page table
then returns to retry the instruction

allocating space on demand

note: the space doesn't have to be initially empty

only change: load from file, etc. instead of allocating empty page

loading program can be merely creating empty page table

everything else can be handled in response to page faults

- no time/space spent loading/allocating unneeded space

mmap

Linux/Unix has a function to “map” a file to memory

```
int file = open("somefile.dat", O_RDWR);

    // data is region of memory that represents file
char *data = mmap(..., file, 0);

    // read byte 6 from somefile.dat
char seventh_char = data[6];

   // modifies byte 100 of somefile.dat
data[100] = 'x';
    // can continue to use 'data' like an array
```

swapping almost mmap

access mapped file for first time, read from disk

- (like swapping when memory was swapped out)

write "mapped" memory, write to disk eventually

- (like writeback policy in swapping)
- use "dirty" bit

extra detail: other processes should see changes

- all accesses to file use same physical memory

Linux maps: list of maps

```
$ cat /proc/self/maps
00400000-0040b000 r-xp 00000000 08:01 48328831        /bin/cat

PCB contains list of `struct vm_area_struct` with:

(shown in this output):

- virtual address start, end
- permissions
- offset in backing file (if any)
- pointer to backing file (if any)

(not shown):

- info about sharing of non-file data …

swapping

early motivation for virtual memory: swapping

using disk (or SSD, ...) as the next level of the memory hierarchy

- how our textbook and many other sources presents virtual memory

OS allocates program space on disk

- own mapping of virtual addresses to location on disk

DRAM is a cache for disk

swapping

early motivation for virtual memory: swapping

using disk (or SSD, ...) as the next level of the memory hierarchy

- how our textbook and many other sources presents virtual memory

OS allocates program space on disk

- own mapping of virtual addresses to location on disk

DRAM is a cache for disk

swapping versus caching

"cache block" $\approx$ physical page

fully associative

- every virtual page can be stored in any physical page

replacement/cache misses managed by the OS

normal cache hits happen in hardware

- hardware's page table lookup
- common case that needs to be very fast

swapping components

- "swap in" a page — exactly like allocating on demand!
  - OS gets page fault — invalid in page table
  - check where page actually is (from virtual address)
  - read from disk
  - eventually restart process
- "swap out" a page
  - OS marks as invalid in the page table(s)
  - copy to disk (if modified)

HDD/SDDs are slow

HDD reads and writes: milliseconds to tens of milliseconds

- minimum size: 512 bytes
- writing tens of kilobytes basically as fast as writing 512 bytes

SSD writes and writes: hundreds of microseconds

- designed for writes/reads of kilobytes (not much smaller)

HDD/SDDs are slow

HDD reads and writes: milliseconds to tens of milliseconds

page tricks generally

deliberately make program trigger page/protection fault

but don't assume page/protection fault is an error

have seperate data structures represent logically allocated memory

- e.g. "addresses `0x7FFF8000` to `0x7FFFFFFFF` are the stack"
- might talk about Linux data structures later (book section 9.7)

page table is for the hardware and not the OS

hardware help for page table tricks

information about the address causing the fault

- e.g. special register with memory address accessed
- harder alternative: OS disassembles instruction, look at registers

(by default) rerun faulting instruction when returning from exception

precise exceptions: no side effects from faulting instruction or after

- e.g. `pushq` that caused did not change `%rsp` before fault
- e.g. instructions reordered after faulting instruction not visible
