#### last time

```
private keys (never shared)
public keys (known to all, derived from private keys)
public-key encryption (encrypt w/ public, decrypt w/ private)
digital signatures (verify w/ public, sign w/ private)
certificate idea:
     "X's public key is ..." message + signature
     signature from trusted 'certificate authority'
chains of certificates
```

## encryption/authentication

common to see symmetric "authenticated encryption"

usually combines *malleable* encryption (confidentiality) and MAC (authenticity)

sometimes this is just called "encryption" (but often encryption is missing authenticity)

if you take crypto theory course, more mathematically definite ideas than confidentiality/authenticity...

(e.g. 'indistinguishably under chosen plaintext attack') (and some definitions overlap confidentiality/authenticity ideas)

#### exercise

exercise: how should website certificates verify identity?

#### how do certificate authorities verify

for web sites, set by CA/Browser Forum

#### organization of:

everyone who ships code with list of valid certificate authorities Apple, Google, Microsoft, Mozilla, Opera, Cisco, Qihoo 360, Brave, ... certificate authorities

decide on rules ("baseline requirements") for what CAs do

### BR domain name identity validation

options involve CA choosing random value and:

sending it to domain contact (with domain registrar) and receive response with it, or

observing it placed in DNS or website or sent from server in other specific way

exercise: problems this doesn't deal with?

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

#### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

#### 'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

#### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

#### 'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

#### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

#### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

'CAA' records in the domain name system

#### additional crypto tools

cryptographic hash functions (summarize data)

'secure' random numbers

key agreement

### motivation: summary for signature

digital signatures typically have size limit

...but we want to sign very large messages

solution: get secure "summary" of message

#### cryptographic hash

$$hash(M) = X$$

given X:

hard to find message other than by guessing

given X, M:

hard to find second message so that hash(second message) = X

#### example uses:

substitute for original message in digital signature building message authentication codes

#### password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

#### password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

problem: with fast hash function, can try lots of guesses fast

#### password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

problem: with fast hash function, can try lots of guesses fast fix: special slow/resource-intensive cryptograph hash functions

. Argon2i

scrypt

PBKDF2

#### random numbers

need a lot of keys that no one else knows

common task: choose a random number

question: what does random mean here?

#### cryptographically secure random numbers

security properties we might want for random numbers:

attacker cannot guess (part of) number better than chance

knowing prior 'random' numbers shouldn't help predict next 'random' numbers

compromising machine now shouldn't reveal older random numbers

# exercise: how to generate?

## /dev/urandom

Linux kernel random number generator

collects "entropy" from hard-to-predict events
e.g. exact timing of I/O interrupts
e.g. some processor's built-in random number circuit

turned into as many random bytes as you want

#### turning 'entropy' into random bytes

lots of ways to do this; one (rough/incomplete) idea:

```
internal variable state
to add 'entropy'
    state ← SecureHash(state + entropy)
to extract value:
    random bytes ← SecureHash(1 + state)
```

random bytes  $\leftarrow$  SecureHash(1 + state) give bytes that can't be reversed to compute state

 $\mathsf{state} \leftarrow \mathsf{SecureHash}(2 + \mathsf{state}) \\ \mathsf{change} \ \mathsf{state} \ \mathsf{so} \ \mathsf{attacker} \ \mathsf{can't} \ \mathsf{take} \ \mathsf{us} \ \mathsf{back} \ \mathsf{to} \ \mathsf{old} \ \mathsf{state} \ \mathsf{if} \ \mathsf{compromised} \\$ 

### just asymmetric?

```
given public-key encryption + digital signatures...
```

why bother with the symmetric stuff?

symmetric stuff much faster

symmetric stuff much better at supporting larger messages

#### key agreement

problem: A has B's public encryption key wants to choose shared secret

#### some ideas:

A chooses a key, sends it encrypted to B A sends a public key encrypted B, B chooses a key and sends it back

## key agreement

problem: A has B's public encryption key wants to choose shared secret

#### some ideas:

A chooses a key, sends it encrypted to B A sends a public key encrypted B, B chooses a key and sends it back

#### alternate model:

both sides generate random values derive public-key like "key shares" from values use math to combine "key shares" kinda like  $\mathsf{A} + \mathsf{B}$  both sending each other public encryption keys

# Diffie-Hellman key agreement (2)

A and B want to agree on shared secret

A chooses random value Y

A sends public value derived from Y ("key share")

B chooses random value Z

B sends public value derived from Z ("key share")

A combines Y with public value from B to get number

B combines Z with public value from A to get number and b/c of math chosen, both get same number

# Diffie-Hellman key agreement (1)

#### math requirement:

```
some f, so f(f(X,Y),Z)=f(f(X,Z),Y) (that's hard to invert, etc.)
```

#### choose X in advance and:

A randomly chooses Y

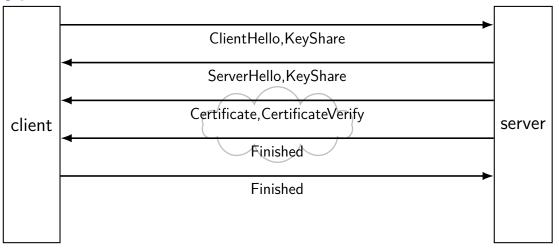

A sends f(X,Y) to B

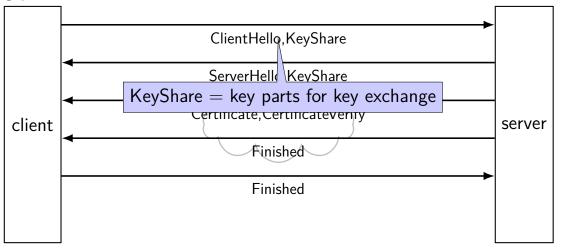

A computes f(f(X,Z),Y)

B randomly chooses Z

B sends f(X,Z) to A

B computes f(f(X,Y),Z)

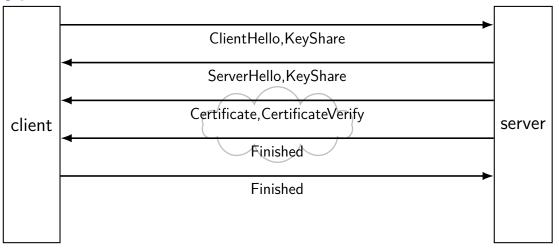

#### **TLS:** after handshake

```
use key shares results to get several keys take hash(something + shared secret) to derive each key separate keys for each direction (server \rightarrow client and vice-versa) often separate keys for encryption and MAC
```

later messages use encryption + MAC + nonces

# things modern TLS usually does

(not all these properties provided by all TLS versions and modes)

```
confidentiality/authenticity
     server = one ID'd by certificate
     client = same throughout whole connection
forward secrecy
     can't decrypt old conversations (data for KeyShares is temporary)
fast
     most communication done with more efficient symmetric ciphers
     1 set of messages back and forth to setup connection
```

# network security summary (1)

```
communicating securely with math
```

```
secret value (shared key, public key) that attacker can't have symmetric: shared keys used for (de)encryption + auth/verify; fast asymmetric: public key used by any for encrypt + verify; slower asymmetric: private key used by holder for decrypt + sign; slower
```

protocol attacks — repurposing encrypt/signed/etc. messages certificates — verifiable forwarded public keys

key agreement — for generated shared-secret "in public" publish key shares from private data combine private data with key share for shared secret

# network security summary (2)

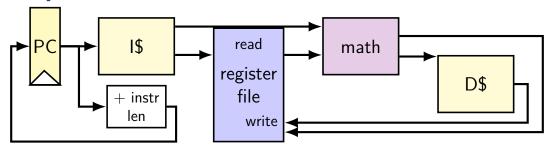

TLS: combine all cryptography stuff to make "secure channel"

```
(things we probably didn't get to:)

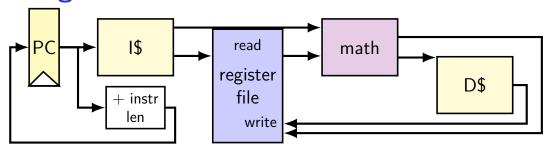

denial-of-service — attacker just disrupts/overloads (not subtle)

firewalls
```

# simple CPU

#### a data hazard

```
// initially %r8 = 800,

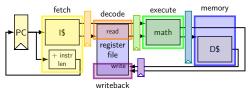

// %r9 = 900, etc.

addq %r8, %r9 // R8 + R9 -> R9

addq %r9, %r8 // R9 + R8 -> R9

addq ...

addq ...
```

	fetch	fetch	/decode	ded	code/exe	ecute	execute/	memory	memory/v	writeback
cycle	PC	rA	rB	R[rB]	R[rB]	rB	sum	rB	sum	rB
0	0×0									
1	0x2	8	9							
2		9	8	800	900	9				
3			•	900	800	8	1700	9		
4						•	1700	8	1700	9
5								•	1700	8

#### a data hazard

```
// initially %r8 = 800,

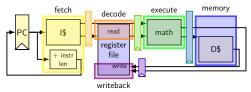

// %r9 = 900, etc.

addq %r8, %r9 // R8 + R9 -> R9

addq %r9, %r8 // R9 + R8 -> R9

addq ...

addq ...
```

	fetch	fetcl	h/decode	de	code/e×	ecute	execute	e/memory	memory	/writeback
cycle	PC	rA	rB	R[rB]	R[rB]	rB	sum	rB	sum	rB
0	0×0				•			•		
1	0x2	8	9							
2		9	8 [	800	900	9				
3				900	800	8	1700	9	]	
4						_	1700	8	1700	9
5			shou	ıld be	170	0		•	1700	8

#### data hazard

```
addq %r8, %r9 // (1)
addq %r9, %r8 // (2)
```

step#	pipeline implementation	ISA specification
1	read r8, r9 for (1)	read r8, r9 for (1)
2	read r9, r8 for (2)	write r9 for (1)
3	write r9 for (1)	read r9, r8 for (2)
4	write r8 for (2)	write r8 ror (2)

pipeline reads older value...

instead of value ISA says was just written

## data hazard compiler solution

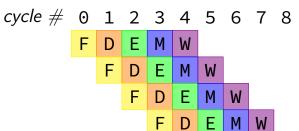

```
addq %r8, %r9
nop
nop
addq %r9, %r8
one solution: change the ISA
     all addqs take effect three instructions later
     (assuming can read register value while it is being written back)
make it compiler's job
problem: recompile everytime processor changes?
```

## data hazard compiler solution

```
addq %r8, %r9
nop
nop
addq %r9, %r8
one solution: change the ISA
     all addqs take effect three instructions later
     (assuming can read register value while it is being written back)
make it compiler's job
problem: recompile everytime processor changes?
```

# stalling/nop pipeline diagram (1)

add %r8, %r9
nop
nop
addq %r9, %r8

# stalling/nop pipeline diagram (1)

```
      cycle # 0 1 2 3 4 5 6 7 8

      add %r8, %r9
      F D E M W

      nop
      F D E M W

      nop
      F D E M W

      addq %r9, %r8
      F D E M W
```

assumption:

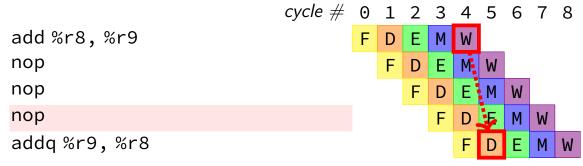

if writing register value register file will return that value for reads

not actually way register file worked in single-cycle CPU (e.g. can read old %r9 while writing new %r9)

# stalling/nop pipeline diagram (2)

# stalling/nop pipeline diagram (2)

if we didn't modify the register file, we'd need an extra cycle

#### data hazard hardware solution

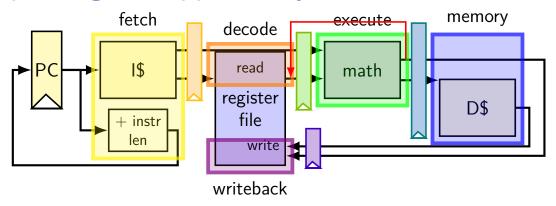

```
addq %r8, %r9
// hardware inserts: nop
// hardware inserts: nop
addq %r9, %r8
how about hardware add nops?
called stalling
extra logic:
    sometimes don't change PC
    sometimes put do-nothing values in pipeline registers
```

#### opportunity

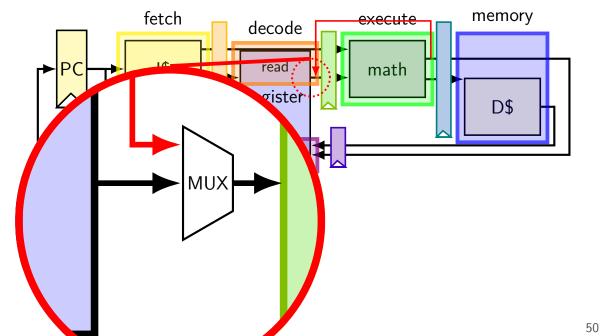

```
// initially %r8 = 800,
// %r9 = 900, etc.
0x0: addq %r8, %r9
0x2: addq %r9, %r8
...
```

fetch/decode decode/execute execute/memory memory/writeback fetch R[rB R[rB] PC rВ rВ rВ cycle rΑ rΒ sum lsum 0 0x0 0x2 8 9 800 900 1700 900 800 1700 1700 9 should be 1700 8 1700

in subq, %r8 is \_\_\_\_\_ addq.

in xorq, %r9 is \_\_\_\_\_ addq.

in andq, %r9 is \_\_\_\_\_ addq.

in andq, %r9 is \_\_\_\_\_ xorq.

A: not forwarded from

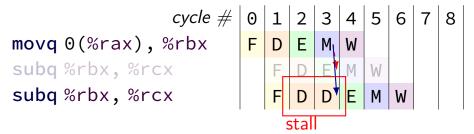

B-D: forwarded to decode from  $\{execute, memory, writeback\}$  stage of

### unsolved problem

combine stalling and forwarding to resolve hazard

assumption in diagram: hazard detected in subq's decode stage (since easier than detecting it in fetch stage)

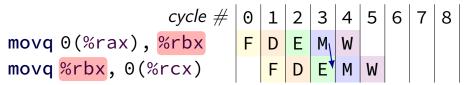

### unsolved problem

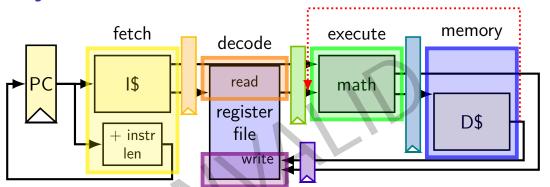

combine stalling and forwarding to resolve hazard

assumption in diagram: hazard detected in subq's decode stage (since easier than detecting it in fetch stage)

### solveable problem

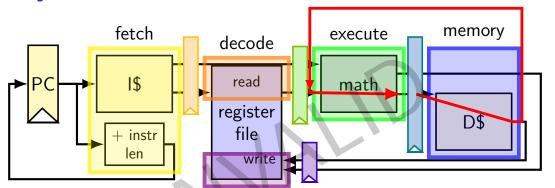

### why can't we...

clock cycle needs to be long enough
to go through data cache AND
to go through math circuits!
(which we were trying to avoid by putting them in separate stages)

### why can't we...

clock cycle needs to be long enough
to go through data cache AND
to go through math circuits!
(which we were trying to avoid by putting them in separate stages)

### hazards versus dependencies

dependency — X needs result of instruction Y?

has potential for being messed up by pipeline
(since part of X may run before Y finishes)

hazard — will it not work in some pipeline?

before extra work is done to "resolve" hazards
multiple kinds: so far, data hazards

```
addq %rax, %rbx
subq %rax, %rcx

```

where are dependencies? which are hazards in our pipeline? which are resolved with forwarding?

# pipeline with different hazards

```
example: 4-stage pipeline:
fetch/decode/execute+memory/writeback

// 4 stage // 5 stage
addq %rax, %r8 // // W
subq %rax, %r9 // W // M
xorq %rax, %r10 // EM // E
andq %r8, %r11 // D // D
```

# pipeline with different hazards

```
example: 4-stage pipeline:
fetch/decode/execute+memory/writeback
             // 4 stage // 5 stage
addq %rax, %r8 // // W
subq %rax, %r9 // W // M
xorq %rax, %r10 // EM // E
andq %r8, %r11 // D // D
addg/andg is hazard with 5-stage pipeline
addq/andq is not a hazard with 4-stage pipeline
```

# pipeline with different hazards

```
example: 4-stage pipeline:
fetch/decode/execute+memory/writeback

// 4 stage // 5 stage
addq %rax, %r8 // // W
subq %rax, %r9 // W // M
xorq %rax, %r10 // EM // E
andq %r8, %r11 // D // D
```

more hazards with more pipeline stages

split execute into two stages: F/D/E1/E2/M/W

result only available near end of second execute stage

where does forwarding, stalls occur?

### "squashed" instructions

on misprediction need to undo partially executed instructions

mostly: remove from pipeline registers

more complicated pipelines: replace written values in cache/registers/etc.

## performance

#### hypothetical instruction mix

kind	portion	cycles (predict not-taken)	cycles (stall)
taken jXX	3%	,	3
non-taken jXX	5%	1	3
others	92%	1*	1*

68

# backup slides

### denial of service (1)

so far: worried about network attacker disrupting confidentiality/authenticity

what if we're just worried about just breaking things well, if they control network, nothing we can do... but often worried about less

## denial of service (2)

my network becomes overloaded?

```
if you just want to inconvenience...
attacker just sends lots of stuff to my server
my server becomes overloaded?
```

but: doesn't this require a lot of work for attacker?

exercise: why is this often not a big obstacle

### denial of service: asymmetry

work for attacker > work for defender
how much computation per message?
 complex search query?
 something that needs tons of memory?
 something that needs to read tons from disk?

how much sent back per message?

resources for attacker > resources of defender

how many machines can attacker use?

### denial of service: reflection/amplification

instead of sending messages directly...attacker can send messages "from" you to third-party

third-party sends back replies that overwhelm network

example: short DNS query with lots of things in response

```
"amplification" = third-party inadvertantly turns small attack into big one
```

#### firewalls

don't want to expose network service to everyone?

#### solutions:

service picky about who it accepts connections from filters in OS on machine with services filters on router

later two called "firewalls"

### firewall rules examples?

ALLOW tcp port 443 (https) FROM everyone

ALLOW tcp port 22 (ssh) FROM my desktop's IP address

BLOCK tcp port 22 (ssh) FROM everyone else

ALLOW from address X to address Y

...

## getting public keys?

browser talking to websites needs public keys of every single website?

not really feasible, but...

#### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

A can generate "certificate" for B:

"B's public key is XXX" AND Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

#### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

#### A can generate "certificate" for B:

"B's public key is XXX" AND Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

#### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

A can generate "certificate" for B: "B's public key is XXX" AND

Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

#### certificate authorities

websites (and others) go to *certificates authorities* (CA) with their public key

certificate authorities sign messages like: "The public key for foo.com is XXX."

signed message called certificate

send certificates to browsers to verify identity

website can forward certificate instead of browser contacting CA directly

#### certificate authorities

websites (and others) go to *certificates authorities* (CA) with their public key

certificate authorities sign messages like: "The public key for foo.com is XXX."

signed message called certificate

send certificates to browsers to verify identity

website can forward certificate instead of browser contacting CA directly

### example web certificate (1)

```
Version: 3 (0x2)
   Serial Number: 7b:df:f6:ae:2e:d7:db:74:d3:c5:77:ac:bc:44:bf:1b
   Signature Algorithm: sha256WithRSAEncryption
   Tssuer:
       countryName
                                = US
       stateOrProvinceName = MI
       localityName
                           = Ann Arbor
       organizationName = Internet2
       organizationalUnitName = InCommon
       commonName
                                = InCommon RSA Server CA
   Validity
       Not Before: Apr 25 00:00:00 2023 GMT
       Not After: Apr 24 23:59:59 2024 GMT
   Subject:
       countryName
                             = US
       stateOrProvinceName = Virginia
       organizationName = University of Virginia
       commonName
                                = canvas.its.virginia.edu
   X509v3 extensions:
. . . .
       X509v3 Subject Alternative Name: DNS:canvas.its.virginia.edu
```

## example web certificate (2)

```
. . . .
    Subject Public Key Info:
        Public Key Algorithm: rsaEncryption
            RSA Public-Key: (2048 bit)
            Modulus:
                00:a2:fb:5a:fb:2d:d2:a7:75:7e:eb:f4:e4:d4:6c:
                94:be:91:a8:6a:21:43:b2:d5:9a:48:b0:64:d9:f7:
                f1:88:fa:50:cf:d0:f3:3d:8b:cc:95:f6:46:4b:42:
Signature Algorithm: sha256WithRSAEncryption
Signature Value:
    24:3a:67:c8:0d:ef:eb:8c:eb:ba:8f:d5:11:d2:1e:ea:44:eb:
    fe:af:93:7d:d9:4a:2h:44:a3:7f:47:50:aa:d1:b3:9c:a8:a8:
. . . .
```

#### certificate chains

That certificate signed by "InCommon RSA Server CA"

CA = certificate authority

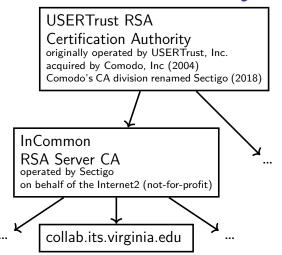

so their public key, comes with my OS/browser? not exactly...

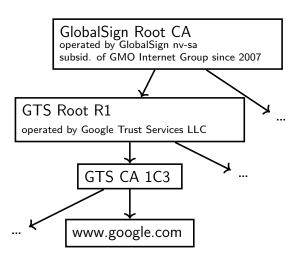

they have their own certificate signed by "USERTrust RSA Certification Authority"

and their public key comes with your OS/browser?

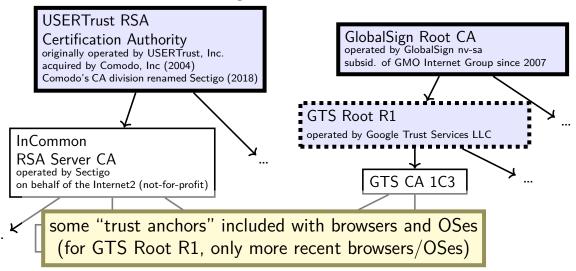

(but both CAs now operated by UK-based Sectigo)

#### certificate hierarchy

### certificate hierarchy

### how many trust anchors?

Mozilla Firefox (as of 27 Feb 2023) 155 trust anchors operated by 55 distinct entities

Microsoft Windows (as of 27 Feb 2023)

237 trust anchors operated by 86 distinct entities

### public-key infrastructure

ecosystem with certificate authorities and certificates for everyone

called "public-key infrastructure"

#### several of these:

for verifying identity of websites for verifying origin of domain name records (kind-of) for verifying origin of applications in some OSes/app stores/etc. for encrypted email in some organizations

...

### key agreement and asym. encryption

can construct public-key encryption from key agreeement

private key: generated random value Y

public key: key share generated from that Y

### key agreement and asym. encryption

can construct public-key encryption from key agreeement

```
private key: generated random value Y

public key: key share generated from that Y

PE(public key, message) =
    generate random value Z
    combine with public key to get shared secret
    use symmetric encryption + MAC using shared secret as keys
    output: (key share generated from Z) (sym. encrypted data) (mac tag)
```

### key agreement and asym. encryption

can construct public-key encryption from key agreeement

private key: generated random value Y

```
public key: key share generated from that Y
PE(public key, message) =
    generate random value Z
     combine with public key to get shared secret
     use symmetric encryption + MAC using shared secret as keys
     output: (key share generated from Z) (sym. encrypted data) (mac tag)
PD(private key, message) =
    extract (key share generated from Z)
     combine with private key to get shared secret, ...
```
