changelog

22 Feb 2024: two-level page tables: fix column label for valid bit on second-level table

22 Feb 2024: pagetable assignmet API: use size_t only, no void

last time

more page table tricks

generalized idea: on exception, maybe fix page table OS tracking memory as list of mappings (separate from page table) page table from HW for hardware

loading from/unloading to files on disk copy-on-write

...

storing page tables in memory

page table base register representing entries as integers

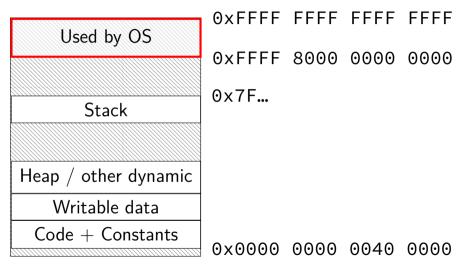

program memory

pagetable assignment

pagetable assignment

simulate page tables (on top of normal program memory) alternately: implement another layer of page tables on top of the existing system's

in assignment:

virtual address \sim arguments to your functions

physical address \sim your program addresses (normal pointers)

pagetable assignment API

```
/* configuration parameters */
#define POBITS ...
#define LEVELS /* later /
size_t ptbr; // page table base register
    // points to page table (array of page table entries)
// lookup "virtual" address 'va' in page table ptbr points to
// return (~OL) if invalid
size t translate(size t va);
// make it so 'va' is valid, allocating one page for its data
// if it isn't already
void page_allocate(size_t va)
```

translate()

with POBITS=12, LEVELS=1:

 $\mathsf{ptbr} = \mathsf{GetPointerToTable}(\begin{array}{c|c} 0 & 0 \\ \hline 1 & 1 \\ \hline 2 & 0 \\ \hline 3 & 1 \\ \hline \dots & \dots \end{array}$

VPN valid? physical

0 0 —

1 1 0x9999

2 0 —

3 1 0x3333

...

```
translate(0x0FFF) == (\text{void*}) ~0L

translate(0x1000) == (\text{void*}) 0x9999000

allocated with posix_memalign

posix_memalign

```
void *result:
error code =
     posix_memalign(&result, alignment, size);
allocate size bytes
choosing address that is multiple of alignment
    can make sure allocation starts at beginning of page
error code indicates if out-of-memory, etc.
fills in result (passed via pointer)
```

posix_memalign

```
void *result:
error code =
     posix_memalign(&result, alignment, size);
allocate size bytes
choosing address that is multiple of alignment
    can make sure allocation starts at beginning of page
error code indicates if out-of-memory, etc.
fills in result (passed via pointer)
```

posix_memalign

```

error code =
     posix_memalign(&result, alignment, size);
allocate size bytes
choosing address that is multiple of alignment
    can make sure allocation starts at beginning of page
error code indicates if out-of-memory, etc.
fills in result (passed via pointer)
```

parts

```
part 1 (next week): LEVELS=1, POBITS=12 and
    translate() OR
    page allocate()
part 2 (two weeks after break): all LEVELS, both functions
    in preparation for code review
    due Weds BFFORF LAB
part 3 (two weeks after break): final submission
    Friday after code review
    most of grade based on this
    will test previous parts again
```

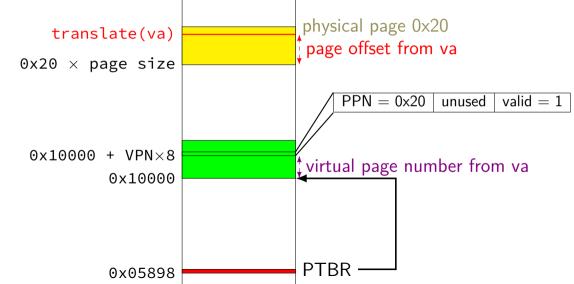

address/page table entry format

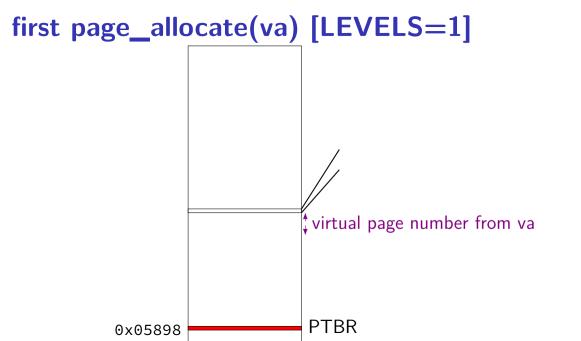

(with POBITS=12, LEVELS=1)

	bits 63–21	bits 20–12	bits 11–1	bit 0
page table entry	physical page number		unused	valid bit
virtual address	unused virtual page number		page offset	
physical address	physical page number		page offset	

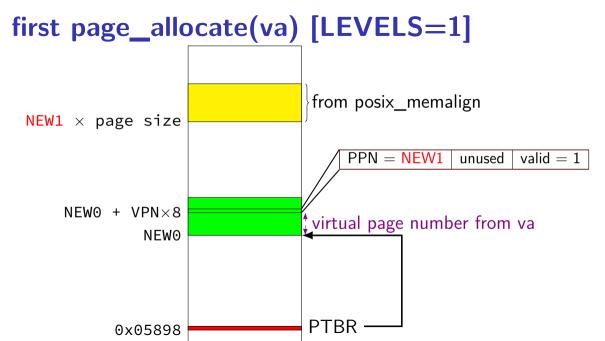

in assignment: value from posix_memalign = physical address

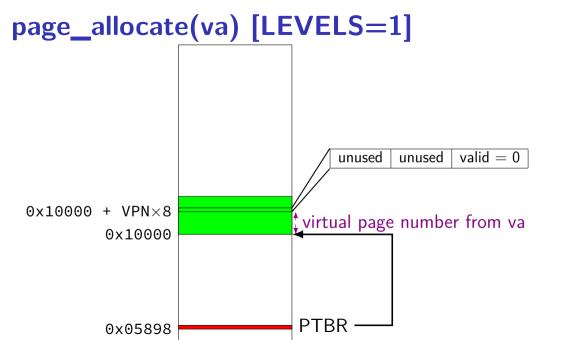

pa = translate(va) [LEVELS=1]

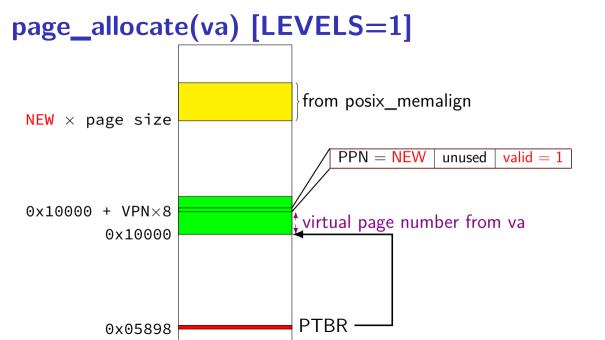

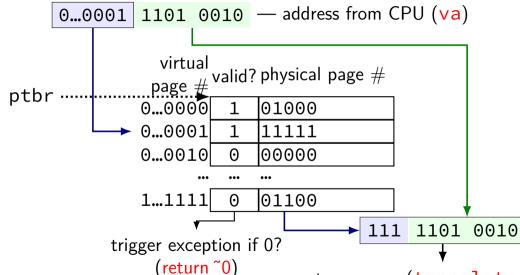

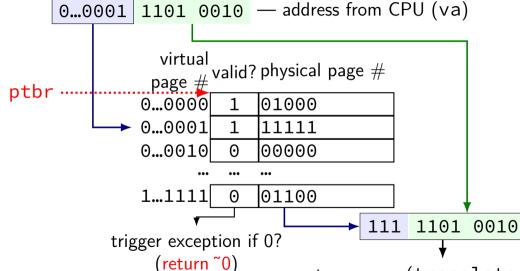

page table lookup (and translate())

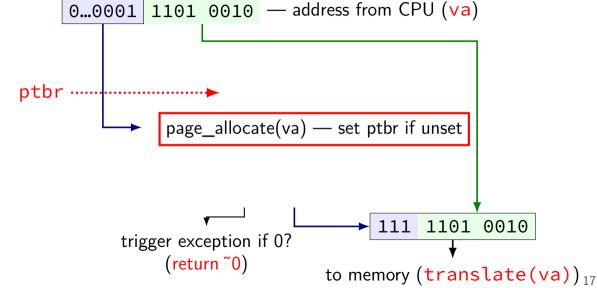

to memory (translate(va))₁₆

page table lookup (and translate())

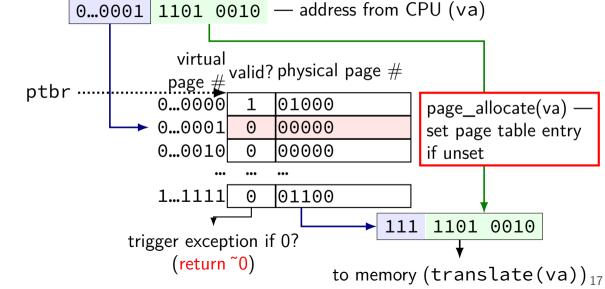

to memory (translate(va))₁₆

page table lookup (and allocate)

page table lookup (and allocate)

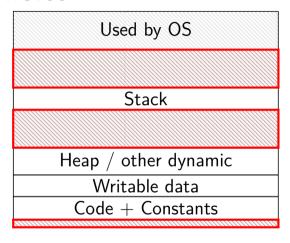

huge page tables

huge virtual address spaces!

impossible to store PTE for every page

how can we save space?

holes

most pages are invalid

saving space

basic idea: don't store (most) invalid page table entries use a data structure other than a flat array want a map — lookup key (virtual page number), get value (PTE) options?

saving space

```
basic idea: don't store (most) invalid page table entries
use a data structure other than a flat array
    want a map — lookup key (virtual page number), get value (PTE)
options?
```

hashtable

actually used by some historical processors but never common

saving space

basic idea: don't store (most) invalid page table entries
use a data structure other than a flat array
want a map — lookup key (virtual page number), get value (PTE)
options?

hashtable

actually used by some historical processors but never common

tree data structure

but not quite a search tree

search tree tradeoffs

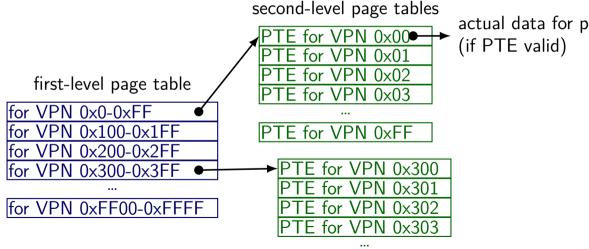

lookup usually implemented in hardware

lookup should be simple solution: lookup splits up address bits (no complex calculations)

lookup should not involve many memory accesses

doing two memory accesses is already very slow solution: tree with many children from each node (far from binary tree's left/right child)

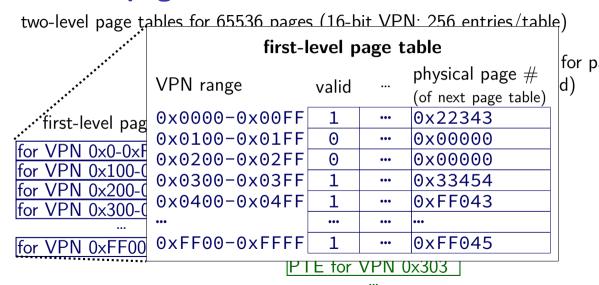

two-level page tables for 65536 pages (16-bit VPN; 256 entries/table)

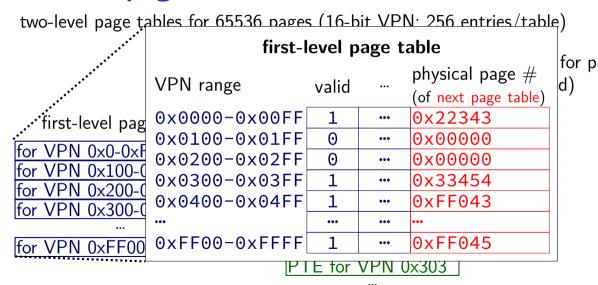

LONG OFF

two-level page tables for 65536 pages (16-bit VPN; 256 entries/table) second-level page tables actual data for p PTE for VPN 0x00 (if PTE valid) E for VPN 0x02 first-level page table for VPN 0x0-0xFF VPN 0×100-0×1FF invalid entries represent big holes 0x200-0x2FFVPN 0x300 for VPN 0x300-0x3FF VPN 0x301 for VPN 0xFF00-0xFFFF

virtual address

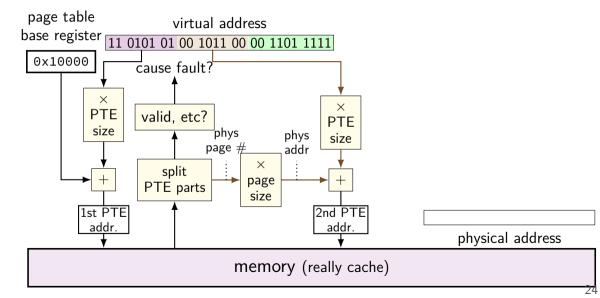

11 0101 01 00 1011 00 00 1101 1111

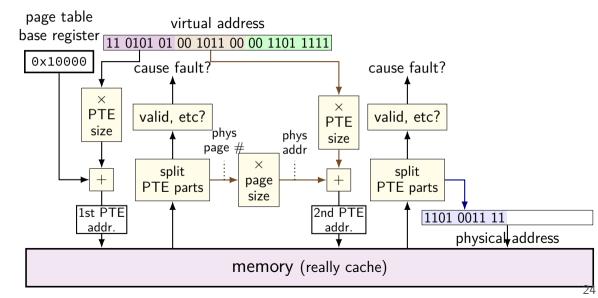

VPN — split into two parts (one per level)

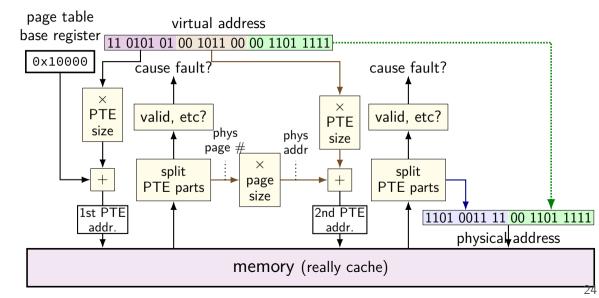

this example: parts equal sized — common, but not required

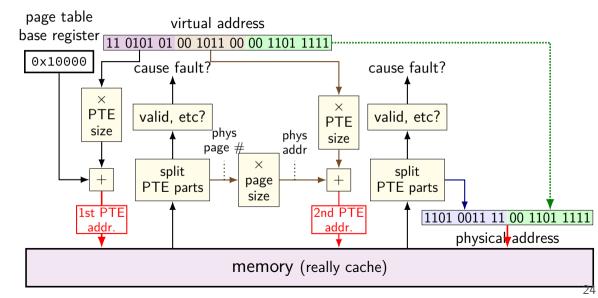

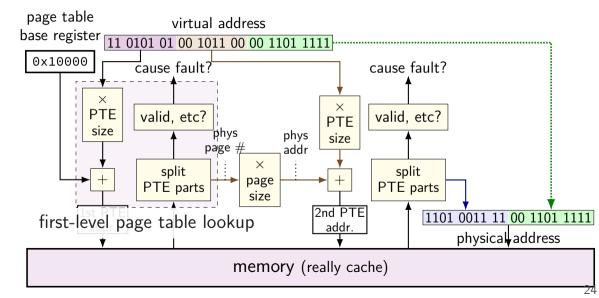

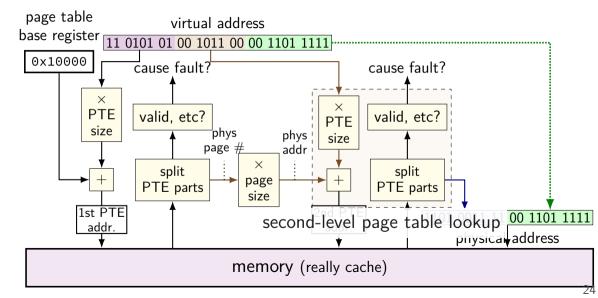

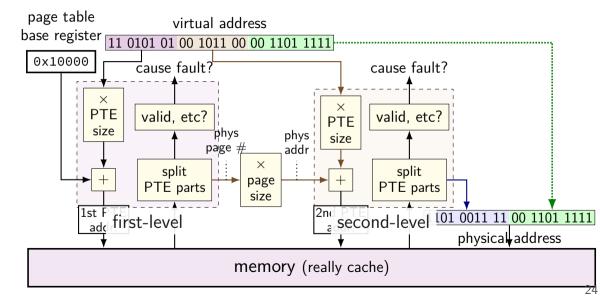

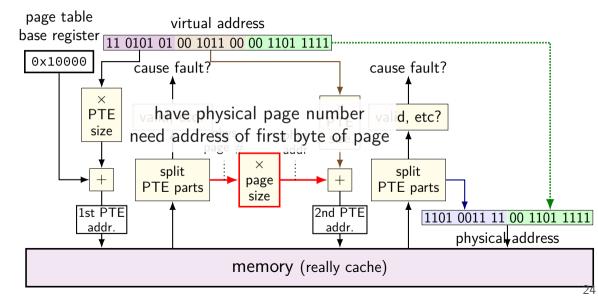

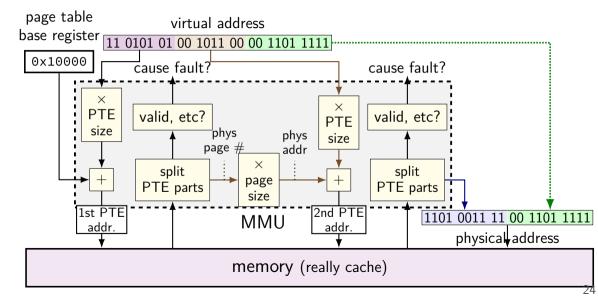

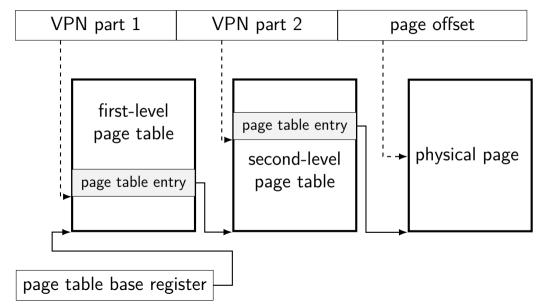

another view

25

multi-level page tables

VPN split into pieces for each level of page table

top levels: page table entries point to next page table usually using physical page number of next page table

bottom level: page table entry points to destination page

validity checks at each level

note on VPN splitting

indexes used for lookup parts of the virtual page number (there are not multiple VPNs)

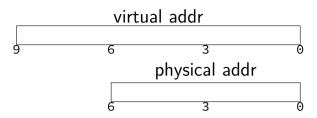

assignment

assignment: variable number of LEVELS

page tables always one page size

means upper bits of virtual address values not used

program memory

system calls, I/O events, etc. run OS code in kernel mode

system calls, I/O events, etc. run OS code in kernel mode

where in memory is this OS code?

system calls, I/O events, etc. run OS code in kernel mode

where in memory is this OS code?

probably have a page table entry pointing to it marked not accessible in user mode

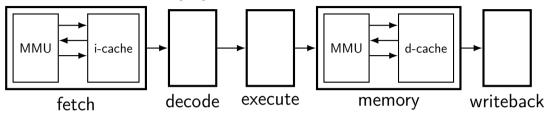

system calls, I/O events, etc. run OS code in kernel mode

where in memory is this OS code?

probably have a page table entry pointing to it marked not accessible in user mode

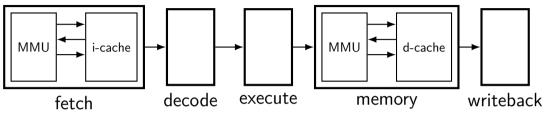

code better not be modified by user program otherwise: uncontrolled way to "escape" user mode

MMUs in the pipeline

up to four memory accesses per instruction

MMUs in the pipeline

up to four memory accesses per instruction challenging to make this fast (topic for a future date)

do we really need a complete copy?

bash	new copy of bash		
Used by OS	Used by OS		
Stack	Stack		
Heap / other dynamic	Heap / other dynamic		
Writable data	Writable data		
Code + Constants	Code + Constants		

do we really need a complete copy?

new copy of bash		
Used by OS		
Stack		
Heap $/$ other dynamic		
Writable data		
Code + Constants		
•		

shared as read-only

do we really need a complete copy?

bash	new copy of bash				
Used by OS	Used by OS				
Stack	Stack				
Heap / other dynamic	Heap / other dynamic				
Writable data	Writable data				
Code + Constants can't be shared? Code + Constants					

trick for extra sharing

```
sharing writeable data is fine — until either process modifies it example: default value of global variables might typically not change (or OS might have preloaded executable's data anyways)
```

can we detect modifications?

trick for extra sharing

sharing writeable data is fine — until either process modifies it example: default value of global variables might typically not change (or OS might have preloaded executable's data anyways)

can we detect modifications?

trick: tell CPU (via page table) shared part is read-only processor will trigger a fault when it's written

copy operation actually duplicates page table both processes share all physical pages but marks pages in both copies as read-only

when either process tries to write read-only page triggers a fault — OS actually copies the page

after allocating a copy, OS reruns the write instruction

pa=translate(va)

swapping

early motivation for virtual memory: swapping

using disk (or SSD, ...) as the next level of the memory hierarchy how our textbook and many other sources presents virtual memory

OS allocates program space on disk own mapping of virtual addresses to location on disk

DRAM is a cache for disk

swapping

early motivation for virtual memory: swapping

using disk (or SSD, ...) as the next level of the memory hierarchy how our textbook and many other sources presents virtual memory

OS allocates program space on disk own mapping of virtual addresses to location on disk

DRAM is a cache for disk

swapping components

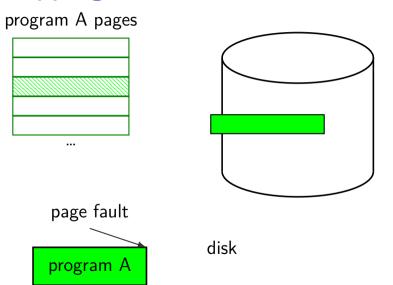

```
"swap in" a page — exactly like allocating on demand!
     OS gets page fault — invalid in page table
     check where page actually is (from virtual address)
     read from disk
    eventually restart process
"swap out" a page
     OS marks as invalid in the page table(s)
     copy to disk (if modified)
```

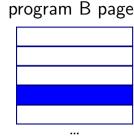

HDD reads and writes: milliseconds to tens of milliseconds minimum size: 512 bytes writing tens of kilobytes basically as fast as writing 512 bytes

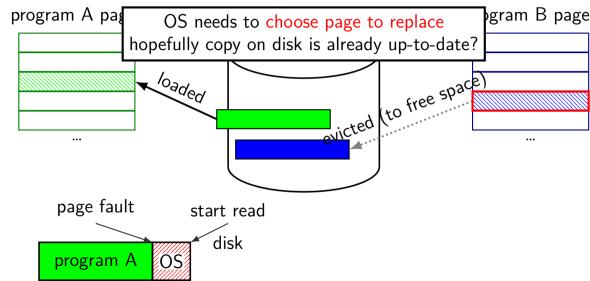

HDD reads and writes: milliseconds to tens of milliseconds minimum size: 512 bytes writing tens of kilobytes basically as fast as writing 512 bytes

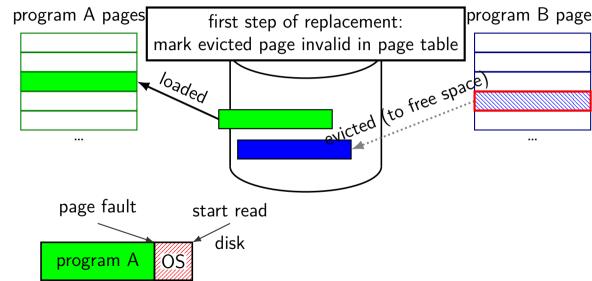

HDD reads and writes: milliseconds to tens of milliseconds minimum size: 512 bytes writing tens of kilobytes basically as fast as writing 512 bytes

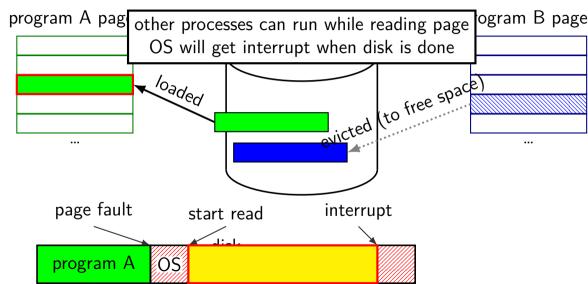

HDD reads and writes: milliseconds to tens of milliseconds minimum size: 512 bytes writing tens of kilobytes basically as fast as writing 512 bytes

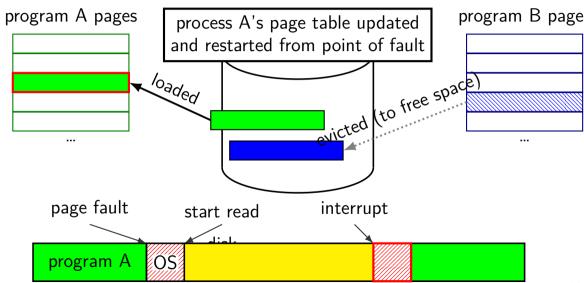

swapping almost mmap

```
access mapped file for first time, read from disk (like swapping when memory was swapped out)
```

write "mapped" memory, write to disk eventually (like writeback policy in swapping) use "dirty" bit

extra detail: other processes should see changes all accesses to file use same physical memory

my desktop: 39-bit physical addresses; 48-bit virtual addresses

4096 byte pages

my desktop: 39-bit physical addresses; 48-bit virtual addresses

4096 byte pages

top 16 bits of 64-bit addresses not used for translation

my desktop: 39-bit physical addresses; 48-bit virtual addresses

4096 byte pages

exercise: how many page table entries? (assuming page table like shown before)

exercise: how large are physical page numbers?

my desktop: 39-bit physical addresses; 48-bit virtual addresses

4096 byte pages

exercise: how many page table entries? (assuming page table like shown before) $2^{48}/2^{12}=2^{36}$ entries

exercise: how large are physical page numbers? 39 - 12 = 27 bits

my desktop: 39-bit physical addresses; 48-bit virtual addresses 4096 byte pages

exercise: how many page table entries? (assuming page table like shown before) $2^{48}/2^{12}=2^{36}$ entries

exercise: how large are physical page numbers? 39 - 12 = 27 bits page table entries are 8 bytes (room for expansion, metadata) trick: power of two size makes table lookup faster

would take up 2^{39} bytes?? (512GB??)
