#### things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

### things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

#### privileged operation: problem

how can hardware (HW) plus operating system (OS) allow: read your own files from hard drive

but disallow:

read others files from hard drive

#### some ideas

OS tells HW 'okay' parts of hard drive before running program code

complex for hardware and for OS

#### some ideas

OS tells HW 'okay' parts of hard drive before running program code

complex for hardware and for OS

OS verifies your program's code can't do bad hard drive access no work for HW, but complex for OS may require compiling differently to allow analysis

#### some ideas

OS tells HW 'okay' parts of hard drive before running program code

complex for hardware and for OS

- OS verifies your program's code can't do bad hard drive access no work for HW, but complex for OS may require compiling differently to allow analysis
- OS tells HW to only allow OS-written code to access hard drive that code can enforce only 'good' accesses requires program code to call OS routines to access hard drive relatively simple for hardware

#### kernel mode

extra one-bit register: "are we in *kernel mode*" other names: privileged mode, supervisor mode, ...

not in kernel mode = *user mode* 

certain operations only allowed in kernel mode privileged instructions

example: talking to any I/O device

#### what runs in kernel mode?

system boots in kernel mode

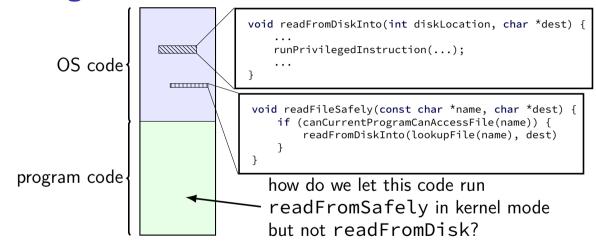

OS switches to user mode to run program code

next topic: when does system switch back to kernel mode? how does OS tell HW where the (trusted) OS code is?

# hardware + system call interface

applications + libraries		
user-mode hardware interface (limited)	system call interface	
	kernel part of OS that runs in kernel mode	
	kernel-mode hardware interface (complete)	
hardware		

#### calling the OS?

# controlled entry to kernel mode (1)

```
special instruction: "make system call"
similar idea as call instruction — jump to function elsewhere
(and allow that function to return later)
```

runs OS code in kernel mode at location specified earlier

OS sets up at boot

location can't be changed without privileged instrution

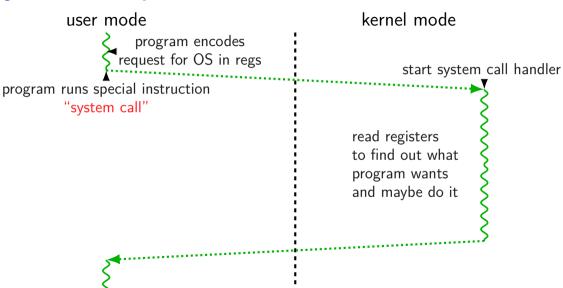

# controlled entry to kernel mode (2)

OS needs to make specified location:

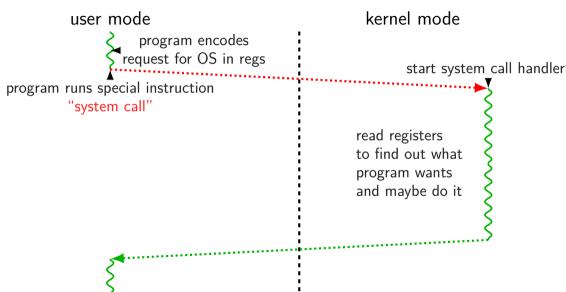

```
figure out what operation the program wants calling convention, similar to function arguments + return value
```

```
be "safe" — not allow the program to do 'bad' things example: checks whether current program is allowed to read file before reading it requires exceptional care — program can try weird things
```

# system call process

# system call process

#### system call terminology

some inconsistency:

```
system call = event of entering kernel mode on request?

system call = whole porcess from beginning to end?

same issue as with 'function call'
```

is it just starting the function, or the whole time the function runs?

### Linux x86-64 system calls

special instruction: syscall

runs OS specified code in kernel mode

# Linux syscall calling convention

before syscall:

%rax — system call number

%rdi, %rsi, %rdx, %r10, %r8, %r9 — args

after syscall:

%rax — return value

on error: %rax contains -1 times "error number"

almost the same as normal function calls

#### Linux x86-64 hello world

```
.globl start
.data
hello_str: .asciz "Hello, World!\n"
.text
start:
  movq $1, %rax # 1 = "write"
  movq $1, %rdi # file descriptor 1 = stdout
  mova $hello str. %rsi
  movg $15, %rdx # 15 = strlen("Hello, World!\n")
  svscall
  movg $60, %rax # 60 = exit
  movq $0, %rdi
  syscall
```

### approx. system call handler

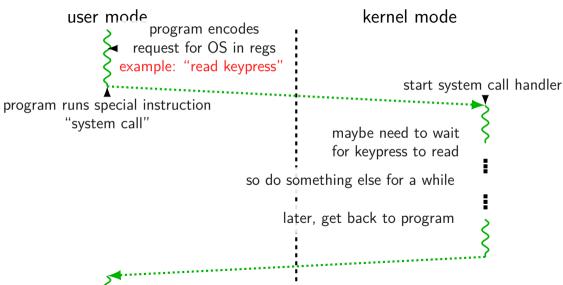

```
sys call table:
    .quad handle_read_syscall
    .quad handle write syscall
    // ...
handle syscall:
    ... // save old PC, etc.
    pushq %rcx // save registers
    pusha %rdi
    . . .
    call *sys call table(,%rax,8)
    . . .
    popq %rdi
    popq %rcx
    return from exception
```

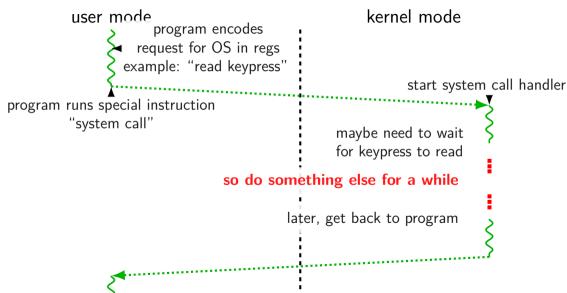

### Linux system call examples

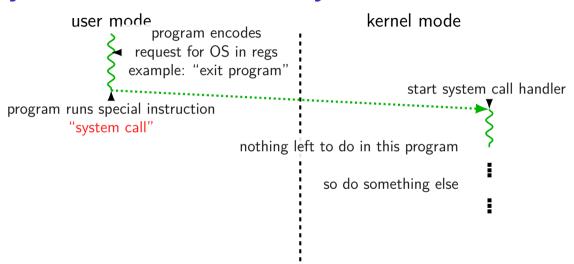

```
mmap, brk — allocate memory
fork — create new process
execve — run a program in the current process
exit — terminate a process
open, read, write — access files
socket, accept, getpeername — socket-related
```

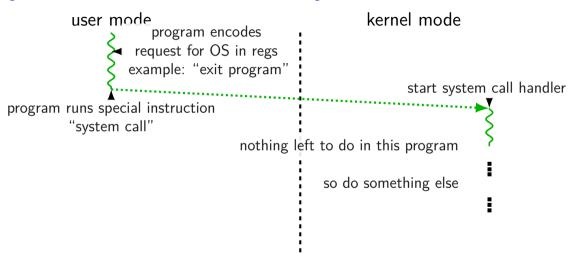

### Linux system call examples

```
mmap, brk — allocate memory
fork — create new process
execve — run a program in the current process
exit — terminate a process
open. read, write — access files
socket, accept, getpeername — socket-related
```

#### system call wrappers

```
library functions to not write assembly:
open:
    movq $2, %rax // 2 = sys_open
    // 2 arguments happen to use same registers
    svscall
    // return value in %eax
    cmp $0, %rax
    il has error
    ret
has error:
    neg %rax
    movq %rax, errno
    movq $-1, %rax
    ret
```

#### system call wrappers

```
library functions to not write assembly:
open:
    movq $2, %rax // 2 = sys_open
    // 2 arguments happen to use same registers
    svscall
    // return value in %eax
    cmp $0, %rax
    il has error
    ret
has error:
    neg %rax
    movq %rax, errno
    movq $-1, %rax
    ret
```

# system call wrapper: usage

```
/* unistd.h contains definitions of:
    O_RDONLY (integer constant), open() */
#include <unistd.h>
int main(void) {
  int file descriptor:
  file descriptor = open("input.txt", O RDONLY);
  if (file_descriptor < 0) {</pre>
      printf("error: \( \) %s\n", strerror(errno));
      exit(1):
  result = read(file descriptor, ...);
```

# system call wrapper: usage

```
/* unistd.h contains definitions of:
    O_RDONLY (integer constant), open() */
#include <unistd.h>
int main(void) {
  int file descriptor:
  file_descriptor = open("input.txt", O_RDONLY);
  if (file_descriptor < 0) {</pre>
      printf("error: "%s\n", strerror(errno));
      exit(1):
  result = read(file descriptor, ...);
```

### strace hello\_world (1)

strace — Linux tool to trace system calls

# strace hello\_world (2)

write(1, "Hello, World!\n", 14)

exit\_group(0)

```
#include <stdio.h>
int main() { puts("Hello, World!"); }
when statically linked:
execve("./hello_world", ["./hello_world"], 0x7ffeb4127f70 /* 28 vars */)
brk(NULL)
                                         = 0 \times 22 f8000
brk(0x22f91c0)
                                         = 0x22f91c0
arch_prctl(ARCH_SET_FS, 0x22f8880)
uname({sysname="Linux", nodename="reiss-t3620", ...}) = 0
readlink("/proc/self/exe", "/u/cr4bd/spring2023/cs3130/slide"..., 4096)
brk(0x231a1c0)
                                         = 0x231a1c0
brk(0x231b000)
                                         = 0x231b000
access("/etc/ld.so.nohwcap", F_OK)
                                        = -1 ENOENT (No such file or
                                                      directory)
```

 $fstat(1, {st mode=S IFCHR|0620, st rdev=makedev(136, 4), ...}) = 0$ 

= 14

### aside: what are those syscalls?

```
execve: run program
brk: allocate heap space
arch_prctl(ARCH_SET_FS, ...): thread local storage pointer
    may make more sense when we cover concurrency/parallelism later
uname: get system information
readlink of /proc/self/exe: get name of this program
access: can we access this file [in this case, a config file]?
fstat: get information about open file
exit group: variant of exit
```

# strace hello\_world (2)

write(1, "Hello, World!\n", 14)

close(3)

exit group(0)

+++ exited with 0 +++

```
#include <stdio.h>
int main() { puts("Hello, World!"); }
when dynamically linked:
execve("./hello_world", ["./hello_world"], 0x7ffcfe91d540 /* 28 vars */)
brk(NULL)
                                         = 0 \times 55 d6 c351 b000
openat(AT_FDCWD, "/etc/ld.so.cache", O_RDONLY|O_CLOEXEC) = 3
fstat(3, {st_mode=S_IFREG|0644, st_size=196684, ...}) = 0
mmap(NULL, 196684, PROT_READ, MAP_PRIVATE, 3, 0) = 0 \times 767762 \times 10^{-1}
close(3)
access("/etc/ld.so.nohwcap", F OK) = -1 ENOENT (No such file or director)
openat(AT_FDCWD, "/lib/x86_64-linux-gnu/libc.so.6", O_RDONLYIO_CLOEXEC) = 3
read(3, "\177ELF\2\1\1\3\0\0\0\0\0\0\0\3\0\0\1\0\0\0"..., 832) = 832
```

#### hardware + system call + library interface

## things programs on portal shouldn't do

read other user's files

modify OS's memory

read other user's data in memory

hang the entire system

modifying another program's memory?

```
Program A
                            Program B
0x10000: .long 42
                            // while A is working:
     // ...
                            movq $99, %rax
     // do work
                            movq %rax, 0x10000
     // ...
     movq 0x10000, %rax
```

modifying another program's memory?

Program A	Program B
0x10000: .long 42 // // do work // movq 0x10000, %rax	<pre>// while A is working: movq \$99, %rax movq %rax, 0x10000</pre>
result: %rax (in A) is	

A. 42 B. 99 C. 0x10000

D. 42 or 99 (depending on timing/program layout/etc)

E. 42 or 99 or program might crash (depending on ...)

F. something else

A. 42 B. 99

modifying another program's memory? Program A Program B 0x10000: .long 42 // while A is working: // ... movq \$99, %rax // do work movq %rax, 0x10000 // ... movq 0x10000, %rax result: %rax (in A) is 42 (always with 'normal' multiuser OSes)

C. 0×10000 D. 42 or 99 (depending on timing/program layout/etc)

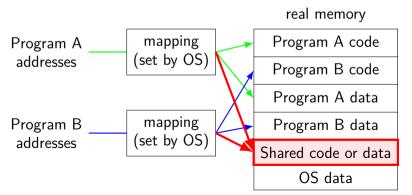

E. 42 or 99 or program might crash (depending on ...) F. something else

#### shared memory

recall: dynamically linked libraries

would be nice not to duplicate code/data...

we can!

#### one way to set shared memory on Linux

```
/* regular file, OR: */
int fd = open("/tmp/somefile.dat", O RDWR);
/* special in-memory file */
int fd = shm open("/name", O RDWR);
/* make file's data accessible as memory */
void *memory = mmap(NULL, size, PROT READ | PROT WRITE,
                    MAP SHARED, fd, 0);
mmap: "map" a file's data into your memory
will discuss a bit more when we talk about virtual memory
part of how Linux loads dynamically linked libraries
```

F. something else

E. 42 or 99 or program might crash (depending on ...)

modifying another program's memory? Program A Program B 0x10000: .long 42 // while A is working: // ... movq \$99, %rax // do work movq %rax, 0x10000 // ... movq 0x10000, %rax result: %rax (in A) is 42 result: might crash (always with 'normal' multiuser OSes) A. 42 B. 99 C. 0x10000 D. 42 or 99 (depending on timing/program layout/etc)

33

#### program crashing?

what happens on processor when program crashes?

other program informed of crash to display message use processor to run some other program

#### program crashing?

what happens on processor when program crashes?

other program informed of crash to display message use processor to run some other program

how does hardware do this?

would be complicated to tell about other programs, etc.

instead: hardware runs designated OS routine

#### exceptions

recall: system calls — software asks OS for help

also cases where hardware asks OS for help different triggers than system calls but same mechanism as system calls:

switch to kernel mode (if not already) call OS-designated function

#### exceptions

recall: system calls — software asks OS for help

also cases where hardware asks OS for help

different triggers than system calls

but same mechanism as system calls:

switch to kernel mode (if not already) call OS-designated function

```
system calls
     intentional — ask OS to do something
errors/events in programs
     memory not in address space ("Segmentation fault")
     privileged instruction
     divide by zero, invalid instruction
(and more we'll talk about later)
```

```
system calls

```

#### external — I/O, etc.

timer — configured by OS to run OS at certain time I/O devices — key presses, hard drives, networks, ... hardware is broken (e.g. memory parity error) asynchronous not triggered by running program

## exceptions [Venn diagram]

# time multiplexing

## time multiplexing

processor:

```
loop.exe
```

```
call get_time
// whatever get_time does
movq %rax, %rbp
million cycle delay

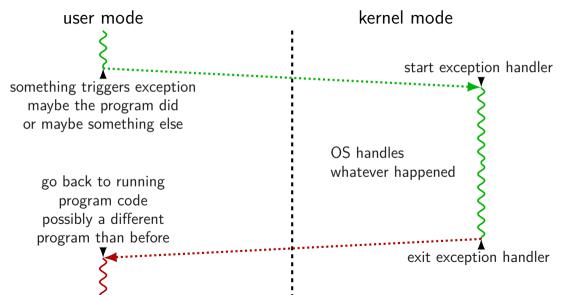

call get_time
// whatever get_time does
subq %rbp, %rax
```

## time multiplexing

processor: loop.exe ssh.exe firefox.exe loop.exe ssh.exe

```
call get_time
    // whatever get time does
movq %rax, %rbp
      – million cycle delay :
call get_time
    // whatever get_time does
subq %rbp, %rax
```

## general exception process

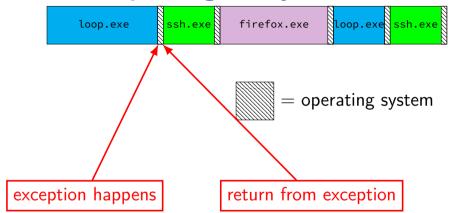

## time multiplexing really

#### time multiplexing really

#### switching programs

OS starts running somehow some sort of exception

saves old registers + program counter + address mapping (optimization: could omit when program crashing/exiting)

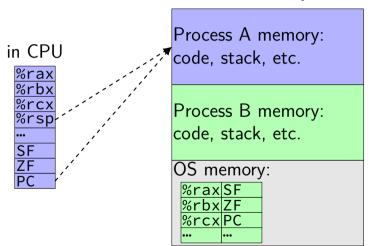

sets new registers + address mapping, jumps to new program counter

called context switch

saved information called context

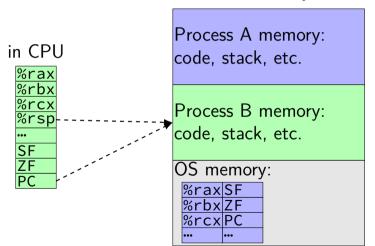

# contexts (A running)

in Memory

## contexts (B running)

in Memory

#### threads

thread = illusion of own processor

own register values

own program counter value

#### threads

thread = illusion of own processor

own register values

own program counter value

actual implementation: many threads sharing one processor

problem: where are register/program counter values when thread not active on processor?

```
system calls
       intentional — ask OS to do something
      rs/events in programs
memory not in address space ("Segmentation fault")
privileged instruction
synchronous
triggered by
current program
errors/events in programs
       privileged instruction
       divide by zero, invalid instruction
```

external — I/O, etc.

timer — configured by OS to run OS at certain time asynchronous I/O devices — key presses, hard drives, networks, ... hardware is broken (e.g. memory parity error)

not triggered by running program

# exception patterns with I/O(1)

#### input — available now:

exception: device says "I have input now"

handler: OS stores input for later

exception (syscall): program says "I want to read input"

handler: OS returns that input

#### input — not available now:

exception (syscall): program says "I want to read input"

handler: OS runs other things (context switch)

exception: device says "I have input now"

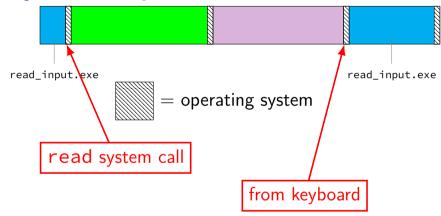

handler: OS retrieves input

handler: (possibly) OS switches back to program that wanted it

# exception patterns with I/O (2)

```
output — ready now:
     exception (syscall): program says "I want to output this'
     handler: OS sends output to deive
output — not ready now
     exception (syscall): program says "I want to output"
     handler: OS realizes device can't accept output yet
     (other things happen)
     exception: device says "I'm ready for output now"
     handler: OS sends output requested earlier
```

# keyboard input timeline

#### review: definitions

exception: hardware calls OS specified routine

many possible reasons

system calls: type of exception

context switch: OS switches to another thread by saving old register values + loading new ones part of OS routine run by exception

# which of these require exceptions? context switches?

- A. program calls a function in the standard library
- B. program writes a file to disk
- C. program A goes to sleep, letting program B run
- D. program exits
- E. program returns from one function to another function
- F. program pops a value from the stack

# which require exceptions [answers] (1)

- A. program calls a function in the standard library no (same as other functions in program; many standard library functions make no system calls (and do not otherwise trigger exceptions for example strlen, pow; also if we consider the calling of a function just the call instruction, then the library functions that do make system calls won't do so until later)
- B. program writes a file to disk yes (requires kernel mode only operations)
- C. program A goes to sleep, letting program B run yes (kernel mode usually required to change the address space to acess program B's memory)

# which require exceptions [answer] (2)

- D. program exits
  yes (requires switching to another program, which requires accessing OS data + other program's memory)
- E. program returns from one function to another function no
- F. program pops a value from the stack no

# which require context switches [answer]

no: A. program calls a function in the standard library

no: B. program writes a file to disk (but might be done if program needs to wait for disk and other things could be run while it does)

yes: C. program A goes to sleep, letting program B run

yes: D. program exits

no: E. program returns from one function to another function

no: F. program pops a value from the stack

#### terms for exceptions

terms for exceptions aren't standardized

```
our readings use one set of terms interrupts = externally-triggered faults = error/event in program trap = intentionally triggered
```

all these terms appear differently elsewhere

#### The Process

```
process = thread(s) + address space
illusion of dedicated machine:
    thread = illusion of own CPU
    (process could have multiple threads — with independent registers)
    address space = illusion of own memory
```

# backup slides

## keeping permissions?

which of the following would still be secure?

- A. performing authorization checks in the standard library in addition to system call handlers
- B. performing authorization checks in the standard library instead of system call handlers
- C. making the user ID a system call argument rather than storing it persistently in the OS's memory

# program memory (two programs)

Program A

Used by OS

Stack

Heap / other dynamic

Writable data

Code + Constants

Program B

Used by OS

Stack

Heap / other dynamic

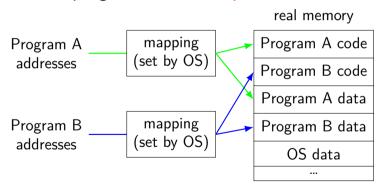

Writable data

Code + Constants

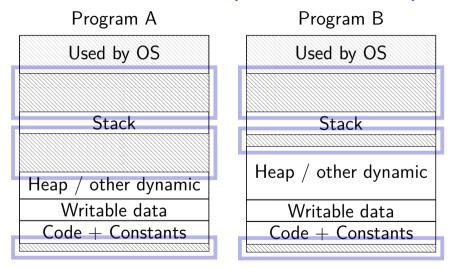

#### address space

programs have illusion of own memory

called a program's address space

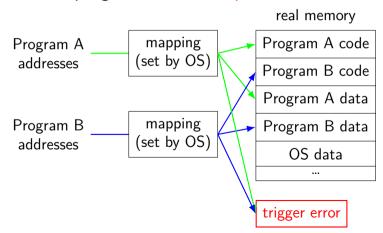

# program memory (two programs)

#### address space

programs have illusion of own memory

called a program's address space

#### address space mechanisms

topic after exceptions

called virtual memory

mapping called page tables

mapping part of what is changed in context switch

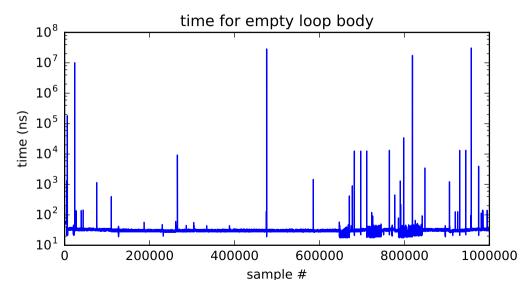

## an infinite loop

```
int main(void) {
     while (1) {
          /* waste CPU time */
If I run this on a shared department machine, can you still use it?
...if the machine only has one core?
```

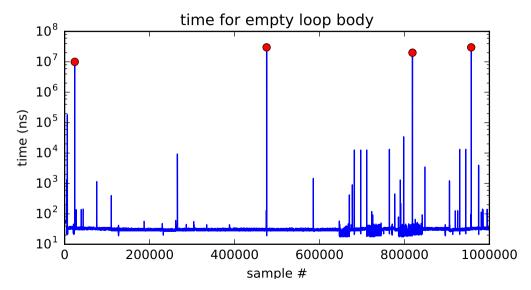

## timing nothing

```
long times[NUM TIMINGS];
int main(void) {
    for (int i = 0; i < N; ++i) {
        long start, end;
        start = get_time();
        /* do nothing */
        end = get_time();
        times[i] = end - start:
    output_timings(times);
same instructions — same difference each time?
```

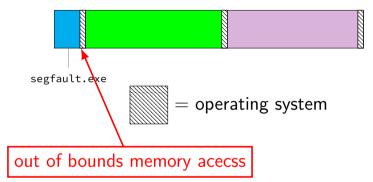

# doing nothing on a busy system

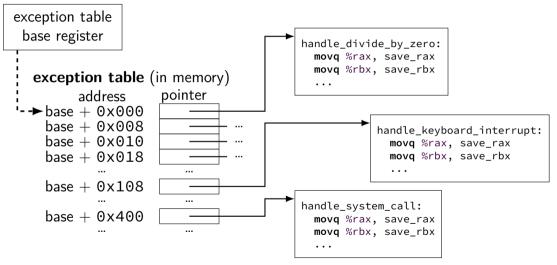

# doing nothing on a busy system

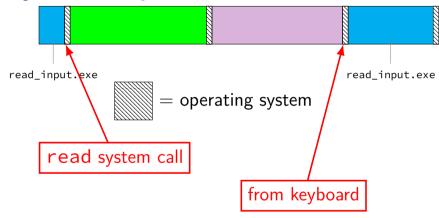

#### crash timeline timeline

# locating exception handlers (one strategy)

# keyboard input timeline

```
handle_timer_interrupt:
    save_old_pc save_pc
    movq %r15, save_r15
    /* key press here */
    movq %r14, save_r14
    ...
```

```
handle timer interrupt:
  save_old_pc save_pc
  movq %r15, save_r15
 /* kev press here */
  movq %r14, save_r14
                    handle keyboard interrupt:
                      save old pc save pc
                      movq %r15, save_r15
                      movq %r14, save r14
                      movq %r13, save r13
```

```
handle timer interrupt:
         save_old_pc save_pc
         movq %r15, save r15
         /* kev press here */
         movq %r14, save_r14
                           handle_keyboard_interrupt:
                             save old pc save pc
                             movq %r15, save_r15
oops, overwrote saved values?
                             movg %r14, save r14
                             movq %r13, save N13
```

## interrupt disabling

CPU supports disabling (most) interrupts

interrupts will wait until it is reenabled

CPU has extra state:

are interrupts enabled? is keyboard interrupt pending? is timer interrupt pending?

```
handle timer interrupt:
 /* interrupts automatically disabled here */
  movq %rsp, save_rsp
  save old pc save pc
  /* key press here */
  impIfFromKernelMode skip_exception_stack
  movg current exception stack, %rsp
skip_set_kernel_stack:
  pusha save rsp
  pushq save pc
  enable_intterupts2
  pusha %r15
  /* interrupt happens here! */
```

```
handle timer interrupt:
 /* interrupts automatically disabled here */
 movq %rsp, save_rsp
  save old pc save pc
 /* key press here */
  impIfFromKernelMode skip_exception_stack
 movg current exception stack, %rsp
skip_set_kernel_stack:
  pusha save rsp
  pushq save pc
  enable_intterupts2
  pusha %r15
  /* interrupt happens here! */
```

```
handle timer interrupt:
 /* interrupts automatically disabled here */
 movq %rsp, save_rsp
  save old pc save pc
 /* key press here */
  impIfFromKernelMode skip_exception_stack
 movg current exception stack, %rsp
skip_set_kernel_stack:
  pusha save rsp
  pushq save pc
  enable_intterupts2
  pusha %r15
  /* interrupt happens here! */
```

#### disabling interrupts

```
automatically disabled when exception handler starts
also can be done with privileged instruction:
change keyboard_parameters:
  disable_interrupts
  /* change things used by
     handle keyboard interrupt here */
  enable_interrupts
```

## exception implementation

detect condition (program error or external event)
save current value of PC somewhere
jump to exception handler (part of OS)
jump done without program instruction to do so

#### exception implementation: notes

I describe a simplified version

real x86/x86-64 is a bit more complicated (mostly for historical reasons)

#### context

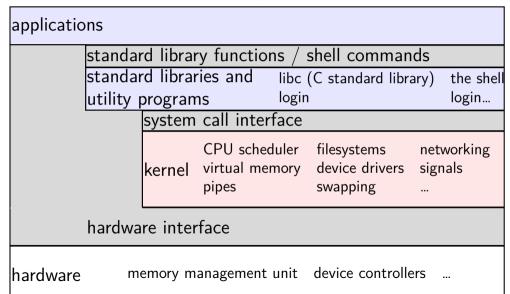

```
all registers values
%rax %rbx, ..., %rsp, ...

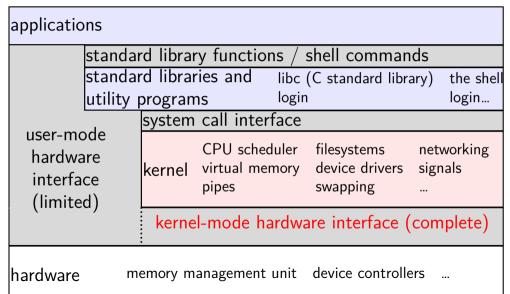

condition codes
program counter

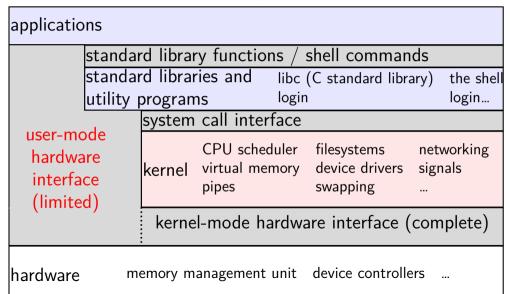

address space (map from program to real addresses)
```

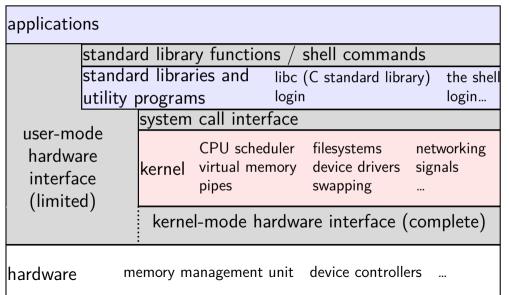

## context switch pseudocode

```
context switch(last, next):
  copy preexception pc last->pc
  mov rax,last->rax
  mov rcx, last->rcx
  mov rdx, last->rdx
  . . .
  mov next->rdx. rdx
  mov next->rcx, rcx
  mov next->rax, rax
  imp next->pc
```

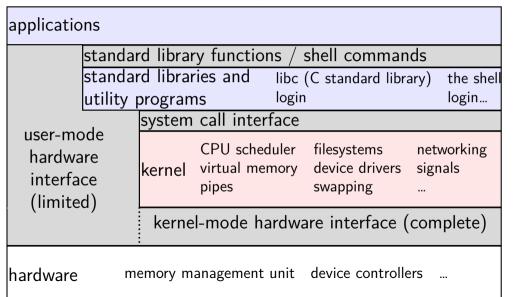

the OS?

the OS?

#### aside: is the OS the kernel?

OS = stuff that runs in kernel mode?

OS = stuff that runs in kernel mode + libraries to use it?

OS = stuff that runs in kernel mode + libraries + utility programs (e.g. shell, finder)?

OS = everything that comes with machine?

no consensus on where the line is

each piece can be replaced separately...

## exception implementation

detect condition (program error or external event)
save current value of PC somewhere
jump to exception handler (part of OS)
jump done without program instruction to do so

## exception implementation: notes

I describe a simplified version

real x86/x86-64 is a bit more complicated (mostly for historical reasons)

#### running the exception handler

hardware saves the old program counter (and maybe more)

identifies location of exception handler via table

then jumps to that location

OS code can save anything else it wants to , etc.
