### last time

### public/private key pairs

give public key to (potentially) everyone keep private key secret (even from correspondents) asymmetric encryption using public key digital signature using private key

#### replay attacks

encrypted/signed/MAC'd/etc. messages can be used out-of-context fix: include needed context/prevent reuse

# getting public keys?

browser talking to websites needs public keys of every single website?

not really feasible, but...

### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

A can generate "certificate" for B:

"B's public key is XXX" AND Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

#### A can generate "certificate" for B:

"B's public key is XXX" AND Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

### certificate idea

let's say A has B's public key already.

if C wants B's public key and knows A's already:

A can generate "certificate" for B:

"B's public key is XXX" AND Sign(A's private key, "B's public key is XXX")

B send copy of their "certificate" to C (most common idea)

if C trusts A, now C has B's public key if C does not trust A, well, can't trust this either

### certificate authorities

instead, have public keys of trusted *certificate authorities* only 10s of them, probably

websites go to certificates authorities with their public key

certificate authorities sign messages like:

"The public key for foo.com is XXX."

these signed messages called "certificates"

# example web certificate (1)

```
Version: 3 (0x2)
   Serial Number: 7b:df:f6:ae:2e:d7:db:74:d3:c5:77:ac:bc:44:bf:1b
   Signature Algorithm: sha256WithRSAEncryption

```

### certificate chains

That certificate signed by "InCommon RSA Server CA"

CA = certificate authority

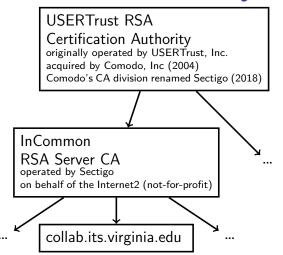

so their public key, comes with my OS/browser? not exactly...

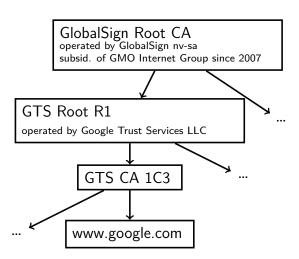

they have their own certificate signed by "USERTrust RSA Certification Authority"

and their public key comes with your OS/browser?

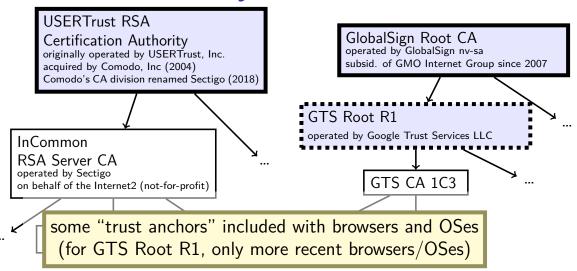

(but both CAs now operated by UK-based Sectigo)

### certificate hierarchy

### certificate hierarchy

### how many trust anchors?

Mozilla Firefox (as of 27 Feb 2023) 155 trust anchors operated by 55 distinct entities

Microsoft Windows (as of 27 Feb 2023)

237 trust anchors operated by 86 distinct entities

## public-key infrastructure

ecosystem with certificate authorities and certificates for everyone

called "public-key infrastructure"

#### several of these:

for verifying identity of websites for verifying origin of domain name records (kind-of) for verifying origin of applications in some OSes/app stores/etc. for encrypted email in some organizations

...

### exercise

exercise: how should website certificates verify identity?

## how do certificate authorities verify

for web sites, set by CA/Browser Forum

#### organization of:

everyone who ships code with list of valid certificate authorities

Apple, Google, Microsoft, Mozilla, Opera, Cisco, Qihoo 360, Brave, ...

certificate authorities

decide on rules ("baseline requirements") for what CAs do

## BR domain name identity validation

options involve CA choosing random value and:

sending it to domain contact (with domain registrar) and receive response with it, or

observing it placed in DNS or website or sent from server in other specific way

exercise: problems this doesn't deal with?

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

#### 'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

'CAA' records in the domain name system

keep their private keys in tamper-resistant hardware

maintain publicly-accessible database of *revoked* certificates some browsers check these, sometimes

### certificate transparency

public logs of every certificate issued some browsers reject non-logged certificates so you can tell if bad certificate exists for your website

'CAA' records in the domain name system

## motivation: summary for signature

mentioned that asymmetric encryption has size limit same problem for digital signatures

solution: sign "summary" of message

how to get summary?

hash function, but...

### cryptographic hash

```
hash(M) = X
```

given X:

hard to find message other than by guessing

given X, M:

hard to find second message so that hash(second message) = H

## cryptographic hash uses

find shorter 'summary' to substitute for data what hashtables use them for, but... we care that adversaries can't cause collisions!

### cryptographic hash uses

find shorter 'summary' to substitute for data what hashtables use them for, but... we care that adversaries can't cause collisions!

```
deal with message limits in signatures/etc.

password hashing — but be careful! [next slide]

constructing message authentication codes

hash message + secret info (+ some other details)
```

### password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

### password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

problem: with fast hash function, can try lots of guesses fast

## password hashing

cryptographic hash functions need (basically) guessing to 'reverse'

idea: store cryptographic hash of password instead of password attacker who gets hash doesn't get password but can still check entered password is correct

problem: with fast hash function, can try lots of guesses fast

fix: special slow/resource-intensive cryptograph hash functions

Argon2i

scrypt

PBKDF2

### random numbers

want keys, etc. to be unguessable and evenly distributed

solution: random numbers

but: many random number functions are not cryptographically secure!

example NOT SECURE: C rand(); Python's random.random better: Python's secrets, os.urandom; Linux getrandom(), /dev/urandom

extra effort to ensure not guessable

need to incorporate "entropy" from unpredictable sources deliberately unstable circuit; exact timing of input/output; etc.

## just asymmetric?

```
given public-key encryption + digital signatures...
```

why bother with the symmetric stuff?

symmetric stuff much faster

symmetric stuff much better at supporting larger messages

## key agreement

problem: A has B's public encryption key wants to choose shared secret

#### some ideas:

A chooses a key, sends it encrypted to B A sends a public key encrypted B, B chooses a key and sends it back

# key agreement

problem: A has B's public encryption key wants to choose shared secret

#### some ideas:

A chooses a key, sends it encrypted to B A sends a public key encrypted B, B chooses a key and sends it back

#### alternate model:

both sides generate random values derive public-key like "key shares" from values use math to combine "key shares" kinda like A + B both sending each other public encryption keys

# Diffie-Hellman key agreement (2)

A and B want to agree on shared secret

A chooses random value Y

A sends public value derived from Y ("key share")

B chooses random value Z

B sends public value derived from Z ("key share")

A combines Y with public value from B to get number

B combines Z with public value from A to get number and b/c of math chosen, both get same number

# Diffie-Hellman key agreement (1)

#### math requirement:

```
some f, so f(f(X,Y),Z)=f(f(X,Z),Y) (that's hard to invert, etc.)
```

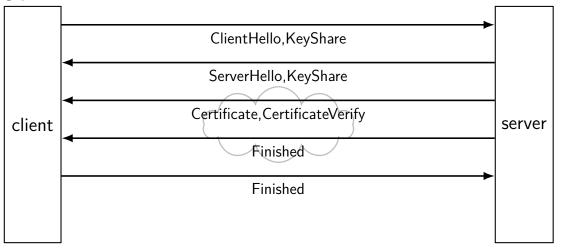

#### choose X in advance and:

A randomly chooses Y B randomly chooses Z

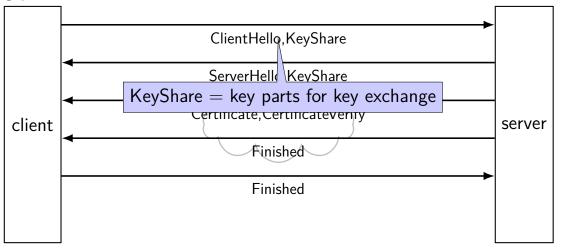

A sends f(X,Y) to B B sends f(X,Z) to A

A computes  $f(f(X,Z),Y) \mid \mathsf{B}$  computes f(f(X,Y),Z)

# typical TLS handshake

# typical TLS handshake

#### TLS: after handshake

```
use key shares results to get several keys take hash(something + shared secret) to derive each key separate keys for each direction (server \rightarrow client and vice-versa) often separate keys for encryption and MAC
```

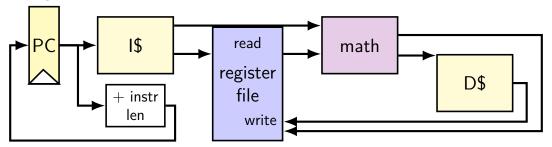

later messages use encryption + MAC + nonces

#### cryptographic tools

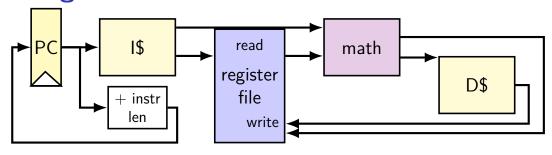

other file/disk encryption or email encryption often combine several techniques like  $\ensuremath{\mathsf{TLS}}$ 

even if "only for encryption"

## simple CPU

## **Latency** — Time for One

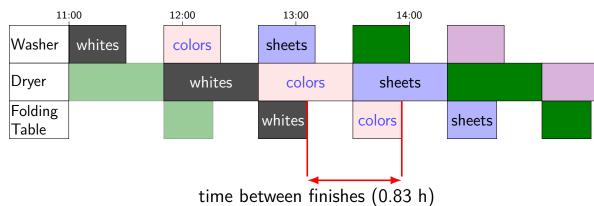

## **Latency** — Time for One

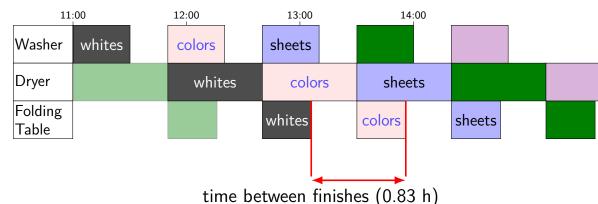

#### **Latency** — **Time for One**

## **Throughput** — Rate of Many

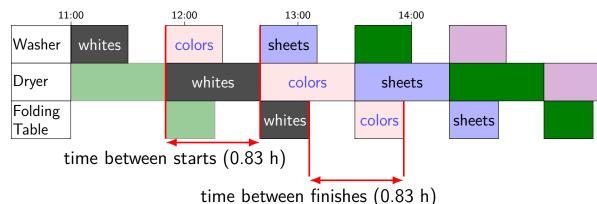

## Throughput — Rate of Many

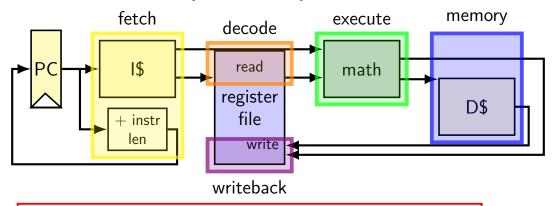

$$\frac{1 \text{ load}}{0.83 \text{h}} = 1.2 \text{ loads/h}$$

## **Throughput** — Rate of Many

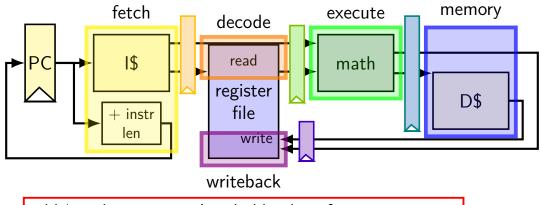

$$\frac{1 \text{ load}}{0.83 \text{h}} = 1.2 \text{ loads/h}$$

## adding stages (one way)

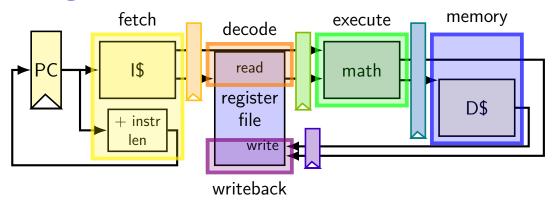

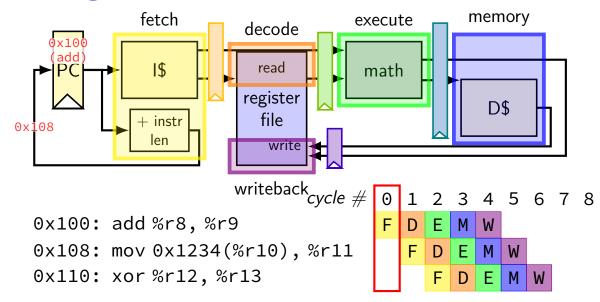

divide running instruction into steps one way: fetch / decode / execute / memory / writeback

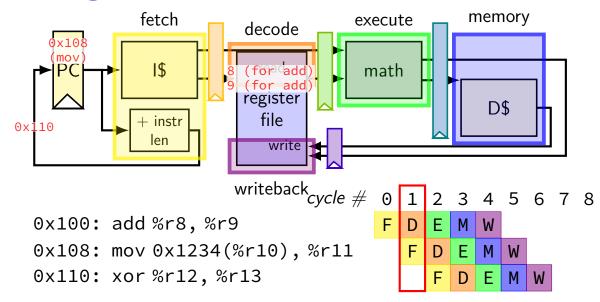

## adding stages (one way)

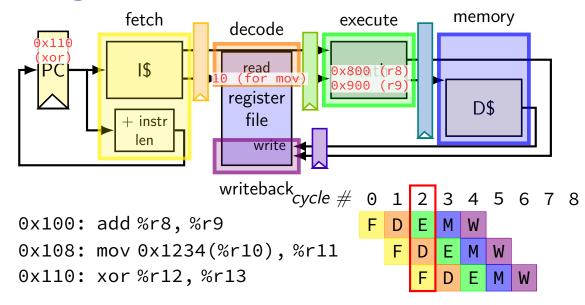

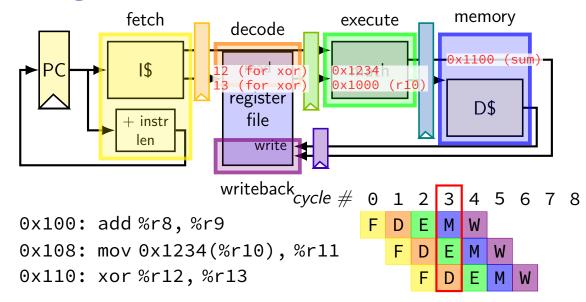

add 'pipeline registers' to hold values from instruction

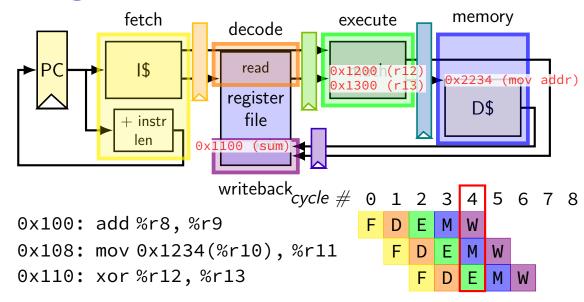

#### why registers?

example: fetch/decode

need to store current instruction somewhere ...while fetching next one

## exercise: throughput/latency (1)

```
cycle \# 0 1 2 3 4 5 6 7 8 0x100: add %r8, %r9 F D E M W 0x108: mov 0x1234(%r10), %r11 F D E M W
```

suppose cycle time is 500 ps

0x110: ...

exercise: latency of one instruction?

A. 100 ps B. 500 ps C. 2000 ps D. 2500 ps E. something else

## exercise: throughput/latency (1)

```
cycle \# 0 1 2 3 4 5 6 7 8 0x100: add %r8, %r9 F D E M W 0x108: mov 0x1234(%r10), %r11 F D E M W
```

0×110: ...

suppose cycle time is 500 ps

exercise: latency of one instruction?

A. 100 ps B. 500 ps C. 2000 ps D. 2500 ps E. something else

exercise: throughput overall?

A. 1 instr/100 ps B. 1 instr/500 ps C. 1 instr/2000ps D. 1 instr/2500 ps

E. something else

# exercise: throughput/latency (2) cycle # 0

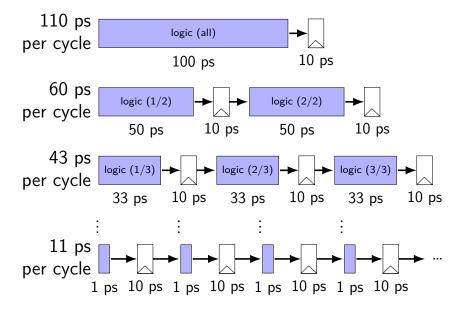

0x110: ...

```
3
0x100: add %r8, %r9
                                             Е
                                        D
0x108: mov 0x1234(%r10), %r11
                                             D
                                                  Е
                                                      M
0x110: ...
                           cycle # 0 1 2 3 4 5 6 7 8
                                  F1 F2 D1 D2 E1 E2 M1 M2 W1 W
0x100: add %r8, %r9
0x108: mov 0x1234(%r10), %r11
                                    F1 F2 D1 D2 E1 E2 M1 M2 W
```

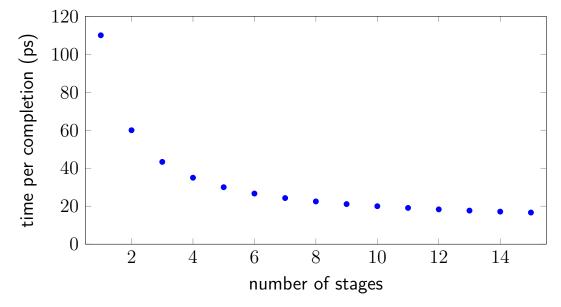

suppose we double number of pipeline stages (to 10) and decrease cycle time from 500 ps to 250 ps

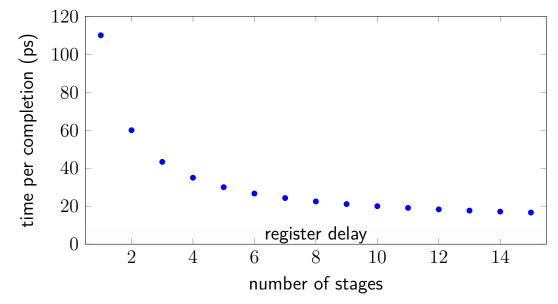

exercise: new throughput?

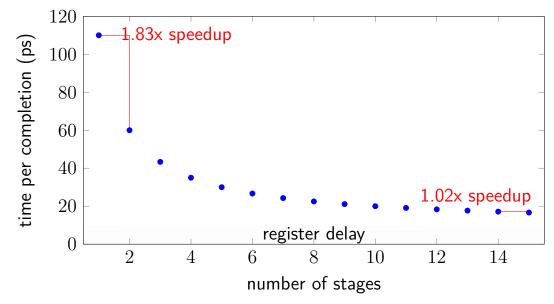

#### diminishing returns: register delays

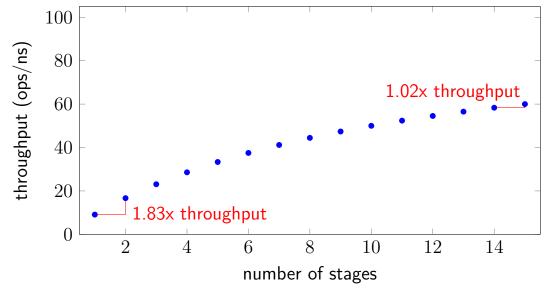

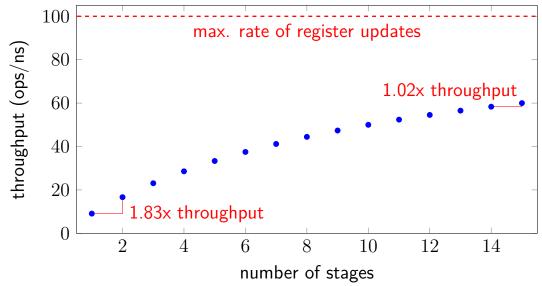

## diminishing returns: register delays

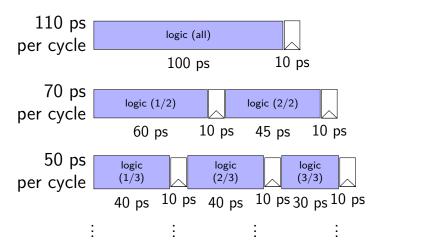

### diminishing returns: uneven split

Can we split up some logic (e.g. adder) arbitrarily?

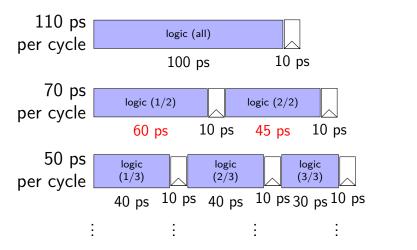

Probably not...

### diminishing returns: uneven split

Can we split up some logic (e.g. adder) arbitrarily?

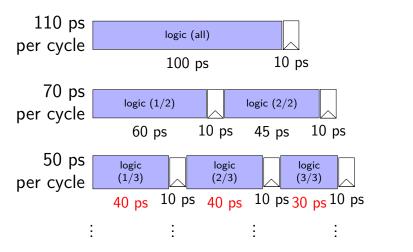

Probably not...

# addq processor: data hazard

```
// initially %r8 = 800,
// %r9 = 900, etc.
addq %r8, %r9
addq %r9, %r8
addq ...
addq ...
```

	fetch	fetc	:h/decode	decode/execute e			execute	/memory	memory/writeback		
cycle	PC	rA	rB	R[rB	R[rB]	rB	sum	rB	sum	rB	
0	0x0		•				•	•			
1	0x2	8	9	]							
2		9	8	800	900	9					
3			•	900	800	8	1700	9	]		
4					•	•	1700	8	1700	9	
5									1700	8	

# addq processor: data hazard

```
// initially %r8 = 800,
// %r9 = 900, etc.
addq %r8, %r9
addq %r9, %r8
addq ...
addq ...
```

	fetch	fetc	:h/decode	decode/execute		execute	/memory	memory/writeback		
cycle	PC	rA	rB	R[rB	R[rB]	rB	sum	sum rB		rB
0	0x0		•			•			•	
1	0x2	8	9	7						
2		9	8 _	800	900	9				
3				900	800	8	1700	9	]	
4								8	1700	9
5			shou	ld be		•	1700	8		

#### data hazard

```
addq %r8, %r9 // (1)
addq %r9, %r8 // (2)
```

step#	pipeline implementation	ISA specification
1	read r8, r9 for (1)	read r8, r9 for (1)
2	read r9, r8 for (2)	write r9 for (1)
3	write r9 for (1)	read r9, r8 for (2)
4	write r8 for (2)	write r8 ror (2)

pipeline reads older value...

instead of value ISA says was just written

#### data hazard compiler solution

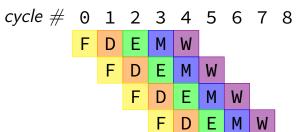

```
addq %r8, %r9
nop
nop
addq %r9, %r8
one solution: change the ISA
     all addqs take effect three instructions later
     (assuming can read register value while it is being written back)
make it compiler's job
problem: recompile everytime processor changes?
```

#### data hazard hardware solution

```
addq %r8, %r9
// hardware inserts: nop
// hardware inserts: nop
addq %r9, %r8
how about hardware add nops?
called stalling
extra logic:
    sometimes don't change PC
    sometimes put do-nothing values in pipeline registers
```

# stalling/nop pipeline diagram (1)

```
add %r8, %r9
(nop)
(nop)
addg %r9, %r8
```

# stalling/nop pipeline diagram (1)

```
      cycle # 0 1 2 3 4 5 6 7 8

      add %r8, %r9
      F D E M W

      (nop)
      F D E M W

      (nop)
      F D E M W

      addq %r9, %r8
      F D E M W
```

assumption:

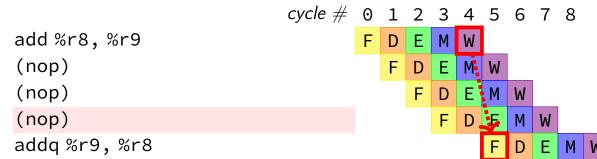

if writing register value register file will return that value for reads

not actually way register file worked in single-cycle CPU (e.g. can read old %r9 while writing new %r9)

# stalling/nop pipeline diagram (2)

# stalling/nop pipeline diagram (2)

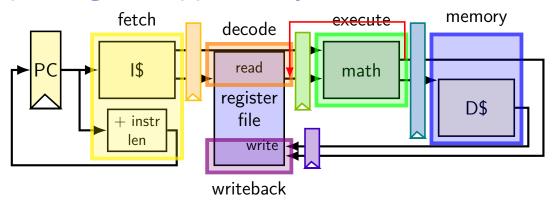

if we didn't modify the register file, we'd need an extra cycle

### opportunity

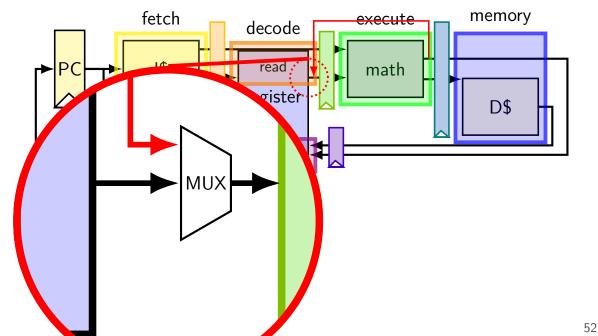

```
// initially %r8 = 800,
// %r9 = 900, etc.
0x0: addq %r8, %r9
0x2: addq %r9, %r8

in subq, %r8 is \_\_\_\_\_ addq.

in xorq, %r9 is \_\_\_\_\_ addq.

in andq, %r9 is \_\_\_\_\_ addq.

in andq, %r9 is \_\_\_\_\_ xorq.

A: not forwarded from

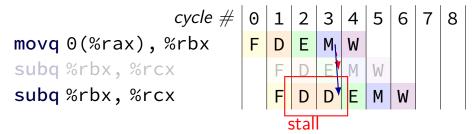

B-D: forwarded to decode from  $\{execute, memory, writeback\}$  stage of

#### unsolved problem

combine stalling and forwarding to resolve hazard

assumption in diagram: hazard detected in subq's decode stage (since easier than detecting it in fetch stage)

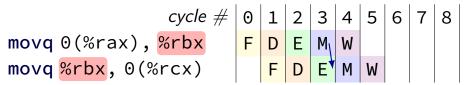

#### unsolved problem

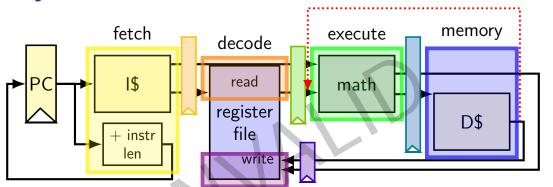

combine stalling and forwarding to resolve hazard

assumption in diagram: hazard detected in subq's decode stage (since easier than detecting it in fetch stage)

#### solveable problem

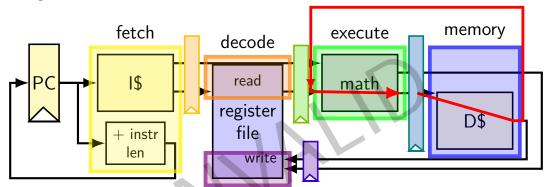

#### why can't we...

clock cycle needs to be long enough
to go through data cache AND
to go through math circuits!
(which we were trying to avoid by putting them in separate stages)

#### why can't we...

clock cycle needs to be long enough to go through data cache AND to go through math circuits! (which we were trying to avoid by putting them in separate stages)

#### hazards versus dependencies

dependency — X needs result of instruction Y?

has potential for being messed up by pipeline
(since part of X may run before Y finishes)

hazard — will it not work in some pipeline?

before extra work is done to "resolve" hazards
multiple kinds: so far, data hazards

```
addq %rax, %rbx

#### "squashed" instructions

on misprediction need to undo partially executed instructions

mostly: remove from pipeline registers

more complicated pipelines: replace written values in cache/registers/etc.

# performance

#### hypothetical instruction mix

### key agreement and asym. encryption

can construct public-key encryption from key agreeement

private key: generated random value Y

public key: key share generated from that Y

### key agreement and asym. encryption

can construct public-key encryption from key agreeement

```
private key: generated random value Y

public key: key share generated from that Y

PE(public key, message) =
    generate random value Z
    combine with public key to get shared secret
    use symmetric encryption + MAC using shared secret as keys
    output: (key share generated from Z) (sym. encrypted data) (mac tag)
```

## key agreement and asym. encryption

can construct public-key encryption from key agreeement

private key: generated random value Y

```
public key: key share generated from that Y
PE(public key, message) =
    generate random value Z
     combine with public key to get shared secret
     use symmetric encryption + MAC using shared secret as keys
     output: (key share generated from Z) (sym. encrypted data) (mac tag)
PD(private key, message) =
    extract (key share generated from Z)
     combine with private key to get shared secret, ...
```

#### random numbers

need a lot of keys that no one else knows

common task: choose a random number

question: what does random mean here?

#### cryptographically secure random numbers

security properties we might want for random numbers:

attacker cannot guess (part of) number better than chance

knowing prior 'random' numbers shouldn't help predict next 'random' numbers

compromising machine now shouldn't reveal older random numbers

exercise: how to generate?

### /dev/urandom

Linux kernel random number generator

```
collects "entropy" from hard-to-predict events
e.g. exact timing of I/O interrupts
e.g. some processor's built-in random number circuit
```

turned into as many random bytes as you want

### turning 'entropy' into random bytes

lots of ways to do this; one (rough/incomplete) idea:

```
internal variable state
to add 'entropy'
     state \leftarrow SecureHash(state + entropy)
to extract value:
      random bytes \leftarrow SecureHash(1 + state)
      give bytes that can't be reversed to compute state
     state \leftarrow SecureHash(2 + state)
      change state so attacker can't take us back to old state if compromised
```

### things modern TLS usually does

(not all these properties provided by all TLS versions and modes)

```
confidentiality/authenticity
     server = one ID'd by certificate
     client = same throughout whole connection
forward secrecy
     can't decrypt old conversations (data for KeyShares is temporary)
fast
     most communication done with more efficient symmetric ciphers
     1 set of messages back and forth to setup connection
```

## denial of service (1)

but often worried about less

so far: worried about network attacker disrupting confidentiality/authenticity

what if we're just worried about just breaking things well, if they control network, nothing we can do...

# denial of service (2)

```
if you just want to inconvenience...
attacker just sends lots of stuff to my server
my server becomes overloaded?
```

my network becomes overloaded?

but: doesn't this require a lot of work for attacker?

exercise: why is this often not a big obstacle

### denial of service: asymmetry

work for attacker > work for defender
how much computation per message?
 complex search query?
 something that needs tons of memory?
 something that needs to read tons from disk?

how much sent back per message?

resources for attacker > resources of defender

how many machines can attacker use?

### denial of service: reflection/amplification

instead of sending messages directly...attacker can send messages "from" you to third-party

third-party sends back replies that overwhelm network

example: short DNS query with lots of things in response

"amplification" = third-party inadvertantly turns small attack into big one

#### firewalls

don't want to expose network service to everyone?

#### solutions:

service picky about who it accepts connections from filters in OS on machine with services filters on router

later two called "firewalls"

### firewall rules examples?

ALLOW tcp port 443 (https) FROM everyone

ALLOW tcp port 22 (ssh) FROM my desktop's IP address

BLOCK tcp port 22 (ssh) FROM everyone else

ALLOW from address X to address Y

...

# network security summary (1)

#### communicating securely with math

```
secret value (shared key, public key) that attacker can't have symmetric: shared keys used for (de)encryption + auth/verify; fast asymmetric: public key used by any for encrypt + verify; slower asymmetric: private key used by holder for decrypt + sign; slower
```

protocol attacks — repurposing encrypt/signed/etc. messages certificates — verifiable forwarded public keys

key agreement — for generated shared-secret "in public" publish key shares from private data combine private data with key share for shared secret

# network security summary (2)

TLS: combine all cryptography stuff to make "secure channel"

denial-of-service — attacker just disrupts/overloads (not subtle)

firewalls

# exercise: forwarding paths (2)
