translation lookaside buffers

special additional cache for last-level page table entries looked by virtual page number can practically be very small and therefore very fast

pthread API — pthread_create, pthread_join
 pthread_join — collect thread function return value + wait for thread
 to finish
 like waitpid: can call when thread already finished

thread joining

pthread_join allows collecting thread return value
if you don't join joinable thread, then memory leak!

thread joining

pthread_join allows collecting thread return value if you don't join joinable thread, then memory leak!

avoiding memory leak?

always join...or

"detach" thread to make it not joinable

pthread_detach

```
void *show_progress(void * ...) { ... }
void spawn_show_progress_thread() {
    pthread t show_progress_thread;
    pthread_create(&show_progress_thread, NULL,
                   show progress, NULL);
    /* instead of keeping pthread t around to join thread later: */
    pthread detach(show progress thread);
int main() {
    spawn show progress thread();
    do other stuff();
           detach = don't care about return value, etc.
            system will deallocate when thread terminates
```

4

starting threads detached

setting stack sizes

a threading race

```
#include <pthread.h>
#include <stdio.h>
void *print_message(void *ignored_argument) {
    printf("In the thread\n");
    return NULL;
int main() {
    printf("About to start thread\n");
    pthread_t the_thread;
    /* assume does not fail */
    pthread create(&the thread, NULL, print message, NULL);
    printf("Done starting thread\n");
    return 0;
```

My machine: outputs In the thread about 4% of the time.

What happened?

a race

returning from main exits the entire process (all its threads) same as calling exit; not like other threads race: main's return 0 or print message's printf first? time main: printf/pthread_create/printf/return print message: printf/return return from main ends all threads in the process

the correctness problem

two threads?

introduces non-determinism

which one runs first?

allows for "race condition" bugs

...to be avoided with synchronization constructs

example application: ATM server

commands: withdraw, deposit

one correctness goal: don't lose money

ATM server (pseudocode) ServerLoop() { while (true) { ReceiveRequest(&operation, &accountNumber, &amount); if (operation == DEPOSIT) { Deposit(accountNumber, amount); } else ... Deposit(accountNumber, amount) { account = GetAccount(accountNumber); account->balance += amount; SaveAccountUpdates(account);

a threaded server?

```
Deposit(accountNumber, amount) {
    account = GetAccount(accountId);
    account->balance += amount;
    SaveAccountUpdates(account);
maybe GetAccount/SaveAccountUpdates can be slow?
    read/write disk sometimes? contact another server sometimes?
maybe lots of requests to process?
    maybe real logic has more checks than Deposit()
all reasons to handle multiple requests at once
```

 \rightarrow many threads all running the server loop

multiple threads

```
main() {
    for (int i = 0; i < NumberOfThreads; ++i) {</pre>
        pthread_create(&server_loop_threads[i], NULL,
                        ServerLoop, NULL);
ServerLoop() {
    while (true) {
        ReceiveRequest(&operation, &accountNumber, &amount);
        if (operation == DEPOSIT) {
            Deposit(accountNumber, amount);
        } else ...
```

the lost write

```
account->balance += amount; (in two threads, same account)
          Thread A
                                       Thread B
mov account->balance, %rax
add amount, %rax
                         context switch
                                mov account->balance, %rax
                                add amount, %rax
                         context switch
mov %rax, account->balance
                         context switch
                                mov %rax, account->balance
```

the lost write

```
account->balance += amount; (in two threads, same account)
          Thread A
                                        Thread B
mov account->balance, %rax
add amount, %rax
                         context switch
                                 mov account->balance, %rax
                                 add amount, %rax
                         context switch
mov %rax, account->balance
                         context switch
                                 mov %rax, account->balance
     lost write to balance
                                      "winner" of the race
```

the lost write

```
account->balance += amount; (in two threads, same account)
          Thread A
                                        Thread B
mov account->balance, %rax
add amount, %rax
                         context switch
                                 mov account->balance, %rax
                                 add amount, %rax
                         context switch
mov %rax, account->balance
                         context switch
                                 mov %rax, account->balance
     lost write to balance
                                      "winner" of the race
    lost track of thread A's money
```

thinking about race conditions (1)

what are the possible values of x? (initially x = y = 0)

Thread A Thread B $x \leftarrow 1$ $y \leftarrow 2$

thinking about race conditions (2)

possible values of x? (initially x = y = 0)

Thread A Thread B $x \leftarrow y + 1 \qquad y \leftarrow 2$ $y \leftarrow y \times 2$

thinking about race conditions (2)

possible values of x? (initially x = y = 0)

thinking about race conditions (3)

what are the possible values of x?

(initially
$$x = y = 0$$
)

Thread A Thread B
$$x \leftarrow 1 \qquad x \leftarrow 2$$

thinking about race conditions (2)

possible values of x? (initially x = y = 0)

Thread A Thread B $x \leftarrow y + 1$ $y \leftarrow 2$ $y \leftarrow y \times 2$

atomic operation

atomic operation = operation that runs to completion or not at all we will use these to let threads work together

most machines: loading/storing (aligned) words is atomic so can't get 3 from $x \leftarrow 1$ and $x \leftarrow 2$ running in parallel aligned \approx address of word is multiple of word size (typically done by compilers)

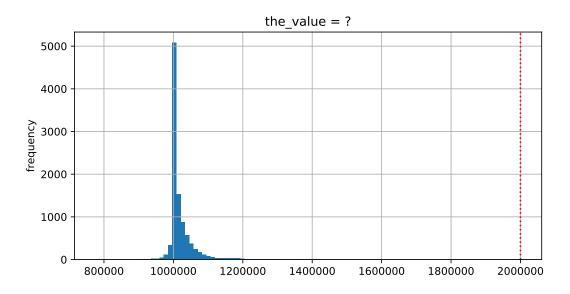

but some instructions are not atomic; examples:

x86: integer add constant to memory location many CPUs: loading/storing values that cross cache blocks
e.g. if cache blocks 0x40 bytes, load/store 4 byte from addr. 0x3E is not atomic

lost adds (program)

```
.global update_loop
update loop:
   addl $1, the_value // the_value (global variable) += 1
   dec %rdi  // argument 1 -= 1
   jg update_loop // if argument 1 >= 0 repeat
   ret
int the_value;
extern void *update_loop(void *);
int main(void) {
    the value = 0;
    pthread t A, B;
    pthread_create(&A, NULL, update_loop, (void*) 1000000);
    pthread create(&B, NULL, update loop, (void*) 1000000);
   pthread_join(A, NULL); pthread_join(B, NULL);
   // expected result: 1000000 + 1000000 = 2000000
   printf("the value = %d\n", the value);
```

lost adds (results)

but how?

probably not possible on single core exceptions can't occur in the middle of add instruction

...but 'add to memory' implemented with multiple steps still needs to load, add, store internally can be interleaved with what other cores do

but how?

probably not possible on single core exceptions can't occur in the middle of add instruction

...but 'add to memory' implemented with multiple steps still needs to load, add, store internally can be interleaved with what other cores do

(and actually it's more complicated than that — we'll talk later)

so, what is actually atomic

```
for now we'll assume: load/stores of 'words' (64-bit machine = 64-bits words)
```

in general: processor designer will tell you

their job to design caches, etc. to work as documented

compilers move loads/stores (1)

compilers move loads/stores (1)

compilers move loads/stores (2)

```
void WaitForOther() {
    is waiting = 1;
    do {} while (!other_ready);
    is waiting = 0;
WaitForOther:
 // compiler optimization: don't set is waiting to 1,
 // (why? it will be set to 0 anyway)
  movl other_ready, %eax // eax <- other_ready</pre>
.L2:
  testl %eax, %eax
  je .L2
                             // while (eax == 0) repeat
  movl $0, is_waiting // is_waiting <- 0
```

compilers move loads/stores (2)

```
void WaitForOther() {
    is waiting = 1;
    do {} while (!other_ready);
    is waiting = 0;
WaitForOther:
 // compiler optimization: don't set is waiting to 1,
 // (why? it will be set to 0 anyway)
  movl other_ready, %eax // eax <- other_ready</pre>
.L2:
  testl %eax, %eax
  je .L2
                             // while (eax == 0) repeat
 movl $0, is_waiting // is_waiting <- 0</pre>
```

compilers move loads/stores (2)

```
void WaitForOther() {
    is waiting = 1;
    do {} while (!other_ready);
    is waiting = 0;
WaitForOther:
 // compiler optimization: don't set is waiting to 1,
  // (why? it will be set to 0 anyway)
 movl other_ready, %eax // eax <- other_ready</pre>
.L2:
  testl %eax, %eax
  je .L2
                             // while (eax == 0) repeat
  movl $0, is_waiting // is_waiting <- 0
```

fixing compiler reordering?

isn't there a way to tell compiler not to do these optimizations?

yes, but that is still not enough!

processors sometimes do this kind of reordering too (between cores)

pthreads and reordering

many pthreads functions prevent reordering everything before function call actually happens before

includes preventing some optimizations
e.g. keeping global variable in register for too long

pthread_create, pthread_join, other tools we'll talk about ... basically: if pthreads is waiting for/starting something, no weird ordering

implementation part 1: prevent compiler reordering

implementation part 2: use special instructions example: x86 mfence instruction

some definitions

mutual exclusion: ensuring only one thread does a particular thing at a time

like checking for and, if needed, buying milk

some definitions

mutual exclusion: ensuring only one thread does a particular thing at a time

like checking for and, if needed, buying milk

critical section: code that exactly one thread can execute at a time

result of critical section

some definitions

mutual exclusion: ensuring only one thread does a particular thing at a time

like checking for and, if needed, buying milk

critical section: code that exactly one thread can execute at a time

result of critical section

lock: object only one thread can hold at a time
interface for creating critical sections

lock analogy

agreement: only change account balances while wearing this hat normally hat kept on table put on hat when editing balance

hopefully, only one person (= thread) can wear hat a time need to wait for them to remove hat to put it on

lock analogy

agreement: only change account balances while wearing this hat normally hat kept on table put on hat when editing balance

hopefully, only one person (= thread) can wear hat a time need to wait for them to remove hat to put it on

"lock (or acquire) the lock" = get and put on hat

"unlock (or release) the lock" = put hat back on table

the lock primitive

```
locks: an object with (at least) two operations: 

acquire or lock — wait until lock is free, then "grab" it 

release or unlock — let others use lock, wakeup waiters
```

typical usage: everyone acquires lock before using shared resource forget to acquire lock? weird things happen

```
Lock(account_lock);
balance += ...;
Unlock(account_lock);
```

the lock primitive

```
locks: an object with (at least) two operations: 

acquire or lock — wait until lock is free, then "grab" it 

release or unlock — let others use lock, wakeup waiters
```

typical usage: everyone acquires lock before using shared resource forget to acquire lock? weird things happen

```
Lock(account_lock);
balance += ...;
Unlock(account_lock);
```

waiting for lock?

when waiting — ideally:

not using processor (at least if waiting a while)

OS can context switch to other programs

pthread mutex

```
exercise
pthread mutex t lock1 = PTHREAD MUTEX INITIALIZER;
pthread mutex t lock2 = PTHREAD MUTEX INITIALIZER;
string one = "init one", two = "init two";
void ThreadA() {
    pthread_mutex_lock(&lock1);
    one = "one in ThreadA"; // (A1)
    pthread_mutex_unlock(&lock1);
    pthread mutex lock(&lock2);
    two = "two in ThreadA"; // (A2)
    pthread mutex unlock(&lock2);
}
void ThreadB() {
    pthread_mutex_lock(&lock1);
    one = "one in ThreadB"; // (B1)
    pthread mutex lock(&lock2);
    two = "two in ThreadB"; // (B2)
    pthread mutex unlock(&lock2);
    pthread mutex unlock(&lock1);
possible values of one/two after A+B run?
```

```
exercise (alternate 1)
pthread_mutex_t lock1 = PTHREAD_MUTEX_INITIALIZER;
 pthread mutex t lock2 = PTHREAD MUTEX INITIALIZER;
 string one = "init one", two = "init two";
void ThreadA() {
     pthread_mutex_lock(&lock2);
     two = "two in ThreadA"; // (A2)
     pthread mutex unlock(&lock2);
     pthread mutex lock(&lock1);
     one = "one in ThreadA"; // (A1)
     pthread mutex unlock(&lock1);
 }
void ThreadB() {
     pthread_mutex_lock(&lock1);
     one = "one in ThreadB"; // (B1)
     pthread mutex lock(&lock2);
     two = "two in ThreadB"; // (B2)
     pthread mutex unlock(&lock2);
     pthread mutex unlock(&lock1);
```

possible values of one/two after A+B run?

```
exercise (alternate 2)
pthread_mutex_t lock1 = PTHREAD_MUTEX_INITIALIZER;
 pthread mutex t lock2 = PTHREAD MUTEX INITIALIZER;
 string one = "init one", two = "init two";
 void ThreadA() {
     pthread_mutex_lock(&lock2);
     two = "two in ThreadA"; // (A2)
     pthread mutex unlock(&lock2);
     pthread mutex lock(&lock1);
     one = "one in ThreadA"; // (A1)
     pthread mutex unlock(&lock1);
 }
 void ThreadB() {
     pthread mutex lock(&lock1);
     one = "one in ThreadB"; // (B1)
     pthread mutex unlock(&lock1);
     pthread mutex lock(&lock2);
     two = "two in ThreadB"; // (B2)
     pthread mutex unlock(&lock2);
possible values of one/two after A+B run?
```

3

POSIX mutex restrictions

pthread_mutex rule: unlock from same thread you lock in

does this actually matter?

depends on how pthread_mutex is implemented

preview: general sync

lots of coordinating threads beyond locks/barriers

will talk about two general tools later:

monitors/condition variables semaphores

big added feature: wait for arbitrary thing to happen

a bad idea

one bad idea to wait for an event:

```
pthread mutex t lock = PTHREAD MUTEX INITIALIZER; bool ready = false;
void WaitForReadv() {
    pthread mutex lock(&lock);
    do {
        pthread_mutex_unlock(&lock);
        /* only time MarkReady() can run *,
        pthread_mutex_lock(&lock);
    } while (!ready);
    pthread mutex unlock(&lock);
void MarkReady() {
    pthread mutex lock(&lock);
    ready = true;
    pthread_mutex_unlock(&lock);
```

wastes processor time; MarkReady can stall waiting for unlock window

beyond locks

```
in practice: want more than locks for synchronization
for waiting for arbtirary events (without CPU-hogging-loop):
     monitors
    semaphores
for common synchornization patterns:
     barriers
     reader-writer locks
higher-level interface:
     transactions
```

barriers

compute minimum of 100M element array with 2 processors algorithm:

compute minimum of 50M of the elements on each CPU one thread for each CPU

wait for all computations to finish

take minimum of all the minimums

barriers

compute minimum of 100M element array with 2 processors algorithm:

compute minimum of 50M of the elements on each CPU one thread for each CPU

wait for all computations to finish

take minimum of all the minimums

barriers API

barrier.Initialize(NumberOfThreads)

barrier.Wait() — return after all threads have waited

idea: multiple threads perform computations in parallel

threads wait for all other threads to call Wait()

barrier: waiting for finish

partial_mins[0],
partial mins[1]

```
barrier.Initialize(2);
       Thread 0
                                 Thread 1
 partial_mins[0] =
     /* min of first
        50M elems */;
                            partial_mins[1] =
                               /* min of last
                                   50M elems */
barrier.Wait();
                            barrier.Wait();
 total min = min(

```

lab next week

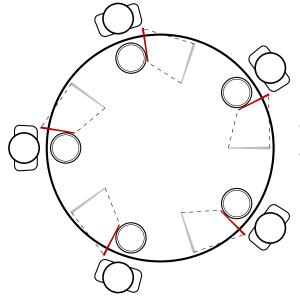

applying solutions to deadlock to classic dining philosphers problem

dining philosophers

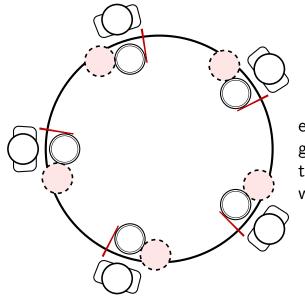

five philosophers either think or eat to eat: grab chopstick on left, then grba chopstick on right, then then eat, then return chopsticks

dining philosophers

everyone eats at the same time? grab left chopstick, then...

dining philosophers

everyone eats at the same time? grab left chopstick, then try to grab right chopstick, ... we're at an impasse

deadlock

```
deadlock — circular waiting for resources
```

```
resource = something needed by a thread to do work locks
CPU time disk space memory
...
```

often non-deterministic in practice

most common example: when acquiring multiple locks

deadlock

```
deadlock — circular waiting for resources
```

```
resource = something needed by a thread to do work locks
CPU time disk space memory
...
```

often non-deterministic in practice

most common example: when acquiring multiple locks

deadlock requirements

mutual exclusion

one thread at a time can use a resource

hold and wait

thread holding a resources waits to acquire another resource

no preemption of resources

resources are only released voluntarily thread trying to acquire resources can't 'steal'

circular wait

there exists a set $\{T_1, \ldots, T_n\}$ of waiting threads such that

 T_1 is waiting for a resource held by T_2 T_2 is waiting for a resource held by T_3

2 is waiting for a resource field

 ${\cal T}_n$ is waiting for a resource held by ${\cal T}_1$

how is deadlock possible?

```
Given list: A, B, C, D, E

RemoveNode(LinkedListNode *node) {
    pthread_mutex_lock(&node->lock);
    pthread_mutex_lock(&node->prev->lock);
    pthread_mutex_lock(&node->next->lock);
    node->next->prev = node->prev; node->prev->next = node->next;
    pthread_mutex_unlock(&node->next->lock); pthread_mutex_unlock(&node->pthread_mutex_unlock(&node->lock);
}
```

Which of these (all run in parallel) can deadlock?

- A. RemoveNode(B) and RemoveNode(C)
- B. RemoveNode(B) and RemoveNode(D)
- C. RemoveNode(B) and RemoveNode(C) and RemoveNode(D)
- D. A and C E. B and C
- F. all of the above G. none of the above

acquiring locks in consistent order (1)

```
MoveFile(Dir* from_dir, Dir* to_dir, string filename) {
   if (from_dir->path < to_dir->path) {
      lock(&from_dir->lock);
      lock(&to_dir->lock);
   } else {
      lock(&to_dir->lock);
      lock(&from_dir->lock);
   }
   ...
}
```

acquiring locks in consistent order (1)

```
MoveFile(Dir* from_dir, Dir* to_dir, string filename) {
   if (from_dir->path < to_dir->path) {
      lock(&from_dir->lock);
      lock(&to_dir->lock);
   } else {
      lock(&to_dir->lock);
      lock(&from_dir->lock);
      lock(&from_dir->lock);
   }
   ...
}
```

any ordering will do e.g. compare pointers

acquiring locks in consistent order (2)

often by convention, e.g. Linux kernel comments:

```
Lock order:
    contex.ldt usr sem
      mmap_sem
        context.lock
Lock order:
1. slab mutex (Global Mutex)
2. node->list lock
slab_lock(page) (Only on some arches and for debugging)
```

infinite resources

or at least enough that never run out

no mutual exclusion

request all resources at once

revoke/preempt resources

no waiting

no shared resources

  pthread mutex unlock(&lock);
```

WaitForFinish timeline 1

WaitForFinish thread	Finish thread
mutex_lock(&lock)	
(thread has lock)	
	<pre>mutex_lock(&lock)</pre>
	(start waiting for lock)
while (!finished)	
<pre>cond_wait(&finished_cv, &lock);</pre>	
(start waiting for cv)	(done waiting for lock)
	finished = true
	<pre>cond_broadcast(&finished_cv)</pre>
(done waiting for cv)	
(start waiting for lock)	
	<pre>mutex_unlock(&lock)</pre>
(done waiting for lock)	
while (!finished)	
(finished now true, so return)	
mutex_unlock(&lock)	

WaitForFinish timeline 2 WaitForFinish thread | mutex_lock(&lock) | | finished = true | | cond_broadcast(&finished_cv) | | mutex_unlock(&lock) | | while (!finished) ...

(finished now true, so return)
mutex unlock(&lock)

why the loop

```
while (!finished) {
   pthread_cond_wait(&finished_cv, &lock);
}
we only broadcast if finished is true
so why check finished afterwards?
```

why the loop

```
while (!finished) {
  pthread_cond_wait(&finished_cv, &lock);
we only broadcast if finished is true
so why check finished afterwards?
pthread cond wait manual page:
    "Spurious wakeups ... may occur."
spurious wakeup = wait returns even though nothing happened
```

```

                                        ...unlock
                                                                        lock
                                                         waiting for
                                                                        ...empty? no
Consume() {
                                                            lock
                                                                        ...dequeue
    pthread_mutex_lock(&lock);
                                                                         ...unlock
    while (buffer.empty()) {
                                                    ...lock
                                                                        return
         pthread_cond_wait(&data_r
                                                    ...empty? yes
                                                    ...unlock/start wait
     item = buffer.dequeue();
     pthread_mutex_unlock(&lock)
                                       0 iterations: Produce() called before Consume()
     return item;
                                         iteration: Produce() signalled, probably
                                          iterations: spurious wakeup or ...?
```

Hoare versus Mesa monitors

Hoare-style monitors signal 'hands off' lock to awoken thread

Mesa-style monitors

any eligible thread gets lock next

(maybe some other idea of priority?)

every current threading library I know of does Mesa-style

```
pthread mutex t lock;
pthread_cond_t data_ready; pthread_cond_t space_ready;
BoundedQueue buffer;
Produce(item) {
    pthread_mutex_lock(&lock);
    while (buffer.full()) { pthread_cond_wait(&space_ready, &lock); }
    buffer.engueue(item);
    pthread_cond_signal(&data_ready);
    pthread mutex unlock(&lock);
Consume() {
    pthread_mutex_lock(&lock);
    while (buffer.empty()) {
        pthread_cond_wait(&data_ready, &lock);
    }
    item = buffer.dequeue();
    pthread_cond_signal(&space_ready);
    pthread_mutex_unlock(&lock);
    return item;
```

```
pthread mutex t lock;
pthread_cond_t data_ready; pthread_cond_t space_ready;
BoundedQueue buffer;
Produce(item) {
    pthread_mutex_lock(&lock);
    while (buffer.full()) { pthread_cond_wait(&space_ready, &lock); }
    buffer.engueue(item);
    pthread_cond_signal(&data_ready);
    pthread mutex unlock(&lock);
Consume() {
    pthread_mutex_lock(&lock);
    while (buffer.empty()) {
        pthread_cond_wait(&data_ready, &lock);
    item = buffer.dequeue();
    pthread_cond_signal(&space_ready);
    pthread_mutex_unlock(&lock);
    return item;
```

```
pthread mutex t lock;
pthread_cond_t data_ready; pthread_cond_t space_ready;
BoundedQueue buffer;
Produce(item) {
    pthread mutex lock(&lock);
    while (buffer.full()) { pthread_cond_wait(&space_ready, &lock); }
    buffer.enqueue(item);
    pthread cond signal (&data ready):
    pt correct (but slow?) to replace with:
Consum pthread_cond_broadcast(&space_ready);
       (just more "spurious wakeups")
        pthread_cond_wait(&data_ready, &lock);
    item = buffer.dequeue();
    pthread_cond_signal(&space_ready);
    pthread_mutex_unlock(&lock);
    return item;
```

return item;

```
pthread_mutex_t lock;
pthread_cond_t data_ready; pthread_cond_t space_ready;
BoundedQueue buffer;
Produce(item) {
    pthread_mutex_lock(&lock);
    while (buffer.full()) { pthread_cond_wait(&space_ready, &lock); }
    buffer.engueue(item);
    pthread_cond_signal(&data_ready);
                                              correct but slow to replace
    pthread mutex unlock(&lock);
                                              data ready and space ready
Consume() {
                                              with 'combined' condvar ready
    pthread_mutex_lock(&lock);
                                              and use broadcast
    while (buffer.empty()) {
        pthread_cond_wait(&data_ready, &lock) (just more "spurious wakeups")
    item = buffer.dequeue();
    pthread_cond_signal(&space_ready);
    pthread_mutex_unlock(&lock);
```

monitor pattern

```
pthread mutex lock(&lock);
while (!condition A) {
    pthread_cond_wait(&condvar_for_A, &lock);
... /* manipulate shared data, changing other conditions */
if (set condition A) {
    pthread_cond_broadcast(&condvar_for_A);
   /* or signal, if only one thread cares */
if (set condition B) {
    pthread cond broadcast(&condvar for B);
    /* or signal, if only one thread cares */
pthread_mutex_unlock(&lock)
```

monitors rules of thumb

never touch shared data without holding the lock

keep lock held for entire operation:

verifying condition (e.g. buffer not full) up to and including manipulating data (e.g. adding to buffer)

create condvar for every kind of scenario waited for

always write loop calling cond_wait to wait for condition X

broadcast/signal condition variable every time you change X

monitors rules of thumb

never touch shared data without holding the lock

keep lock held for entire operation:

verifying condition (e.g. buffer not full) up to and including manipulating data (e.g. adding to buffer)

create condvar for every kind of scenario waited for

always write loop calling cond_wait to wait for condition X

broadcast/signal condition variable every time you change X

correct but slow to...

broadcast when just signal would work broadcast or signal when nothing changed use one condvar for multiple conditions

mutex/cond var init/destroy

```
pthread_mutex_t mutex;
pthread cond t cv;
pthread_mutex_init(&mutex, NULL);
pthread_cond_init(&cv, NULL);
// --OR--
pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
pthread cond t cv = PTHREAD COND INITIALIZER;
// and when done:
pthread cond destroy(&cv);
pthread mutex destroy(&mutex);
```

wait for both finished

```
// MISSING: init calls, etc.
pthread mutex t lock;
bool finished[2];
pthread_cond_t both_finished_cv;
void WaitForBothFinished() {
  pthread_mutex_lock(&lock);
  while (
   pthread_cond_wait(&both_finished_cv, &lock);
  pthread_mutex_unlock(&lock);
void Finish(int index) {
  pthread_mutex_lock(&lock);
  finished[index] = true;
  pthread_mutex_unlock(&lock);
```

wait for both finished

```
A. finished[0] && finished[1]
// MISSING: init calls, etc.
                                 B. finished[0] || finished[1]
pthread mutex t lock;
                                 C.!finished[0] || !finished[1]
bool finished[2];
                                 D. finished[0] != finished[1]
pthread_cond_t both_finished_cv;
                                 E. something else
void WaitForBothFinished() {
  pthread_mutex_lock(&lock);
  while (______
   pthread_cond_wait(&both_finished_cv, &lock);
  pthread_mutex_unlock(&lock);
void Finish(int index) {
  pthread_mutex_lock(&lock);
  finished[index] = true;
  pthread_mutex_unlock(&lock);
```

wait for both finished

```
// MISSING: init calls, etc.
pthread mutex t lock;
                           A. pthread cond signal(&both finished cv)
bool finished[2];
                           B. pthread_cond_broadcast(&both_finished_cv)
pthread_cond_t both_fini
                           C. if (finished[1-index])
                                   pthread cond singal(&both finished cv);
void WaitForBothFinished D if (finished[1-index])
  pthread_mutex_lock(&lo
                                   pthread_cond_broadcast(&both_finished_cv);
                           E. something else
  while (
    pthread_cond_wait(&both_finished_cv, &lock);
  pthread_mutex_unlock(&lock);
void Finish(int index) {
  pthread_mutex_lock(&lock);
  finished[index] = true;
  pthread mutex unlock(&lock);
```

monitor exercise: barrier

suppose we want to implement a one-use barrier; fill in blanks:

```
struct BarrierInfo {
    pthread mutex t lock;
    int total_threads; // initially total # of threads
    int number_reached; // initially 0
};
void BarrierWait(BarrierInfo *b) {
    pthread mutex lock(&b->lock);
    ++b->number reached;
    if (b->number_reached == b->total_threads) {
    } else {
    pthread mutex unlock(&b->lock);
```
