# last time (1)

#### locality — temporal and spatial

temporal: same thing again soon spatial: nearby thing soon natural properties of programs some taken advantage of by compiler (register allocation)

#### direct-mapped caches

divide memory, cache into blocks always power-of-two size blocks, number of 'rows' in cache one place to put each block of memory in the cache

# last time (2)

#### direct-mapped cache lookup

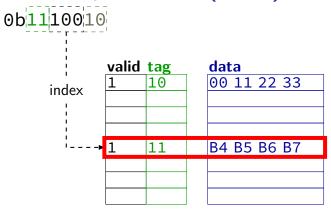

```
divide address into tag / (set) index / (block) offset b-bit block offset — where in 2^b block is byte? s-bit set index — which of 2^s rows of cache to use? tag — which block from memory is stored here? (could store whole block address instead of tag, just saving space)
```

#### instruction v data caches

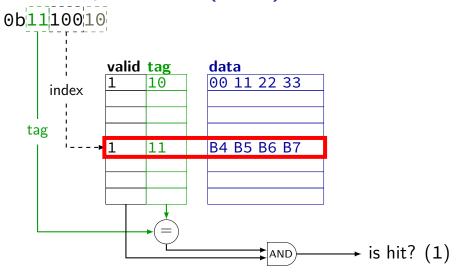

#### alignment and C code

want to avoid splitting things across blocks better start at beginning of block (= multiple of block size)

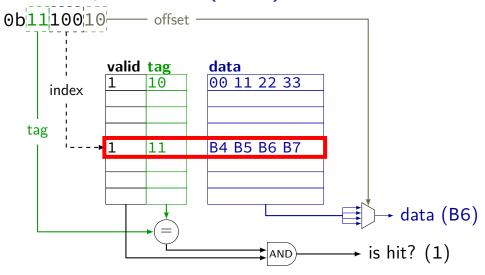

## cache operation (read)

# cache operation (read)

# cache operation (read)

# C and cache misses (warmup 1)

```
int array[4];
...
int even_sum = 0, odd_sum = 0;
even_sum += array[0];
odd_sum += array[1];
even_sum += array[2];
odd_sum += array[3];
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

How many data cache misses on a 1-set direct-mapped cache with 8B blocks?

### some possiblities

Q1: how do cache blocks correspond to array elements? not enough information provided!

#### aside: alignment

compilers and malloc/new implementations usually try align values align = make address be multiple of something

most important reason: don't cross cache block boundaries

# C and cache misses (warmup 2)

```
int array[4];
int even_sum = 0, odd_sum = 0;
even_sum += array[0];
even_sum += array[2];
odd_sum += array[1];
odd_sum += array[3];
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

Assume array[0] at beginning of cache block.

How many data cache misses on a 1-set direct-mapped cache with 8B blocks?

# C and cache misses (warmup 3)

```
int array[8];
...
int even_sum = 0, odd_sum = 0;
even_sum += array[0];
odd_sum += array[1];
even_sum += array[2];
odd_sum += array[3];
even_sum += array[4];
odd_sum += array[5];
even_sum += array[6];
odd_sum += array[7];
```

Assume everything but array is kept in registers (and the compiler does not do anything funny), and array[0] at beginning of cache block.

How many data cache misses on a **2**-set direct-mapped cache with 8B blocks?

# arrays and cache misses (1)

```
int array[1024]; // 4KB array
int even_sum = 0, odd_sum = 0;
for (int i = 0; i < 1024; i += 2) {
    even_sum += array[i + 0];
    odd_sum += array[i + 1];
}</pre>
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

How many data cache misses on a 2KB direct-mapped cache with 16B cache blocks?

# arrays and cache misses (2)

```
int array[1024]; // 4KB array
int even_sum = 0, odd_sum = 0;
for (int i = 0; i < 1024; i += 2)
    even_sum += array[i + 0];
for (int i = 0; i < 1024; i += 2)
    odd_sum += array[i + 1];</pre>
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

How many *data cache misses* on a 2KB direct-mapped cache with 16B cache blocks?

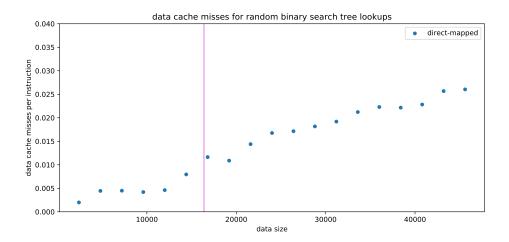

# arrays and cache misses (2b)

```
int array[1024]; // 4KB array
int even_sum = 0, odd_sum = 0;
for (int i = 0; i < 1024; i += 2)
    even_sum += array[i + 0];
for (int i = 0; i < 1024; i += 2)
    odd_sum += array[i + 1];</pre>
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

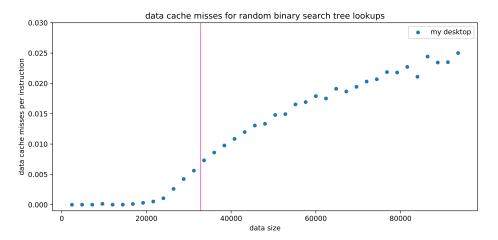

How many *data cache misses* on a 4KB direct-mapped cache with 16B cache blocks?

# simulated misses: BST lookups

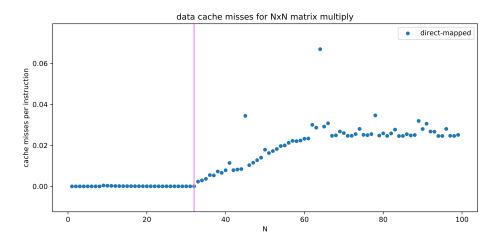

(simulated 16KB direct-mapped data cache)

### actual misses: BST lookups

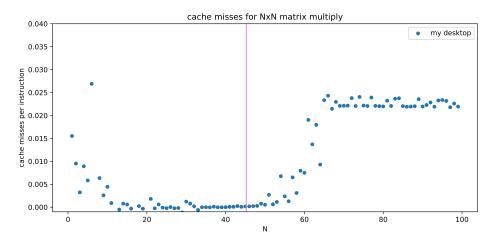

(actual 32KB more complex data cache) (only one set of measurements + other things on machine)

### simulated misses: matrix multiplies

(simulated 16KB direct-mapped data cache)

### actual misses: matrix multiplies

(actual 32KB more complex data cache) (only one set of measurements + other things on machine)

### misses with skipping

```
int array1[512]; int array2[512];
...
for (int i = 0; i < 512; i += 1)
    sum += array1[i] * array2[i];
}</pre>
```

Assume everything but array1, array2 is kept in registers (and the compiler does not do anything funny).

About how many data cache misses on a 2KB direct-mapped cache with 16B cache blocks?

Hint: depends on relative placement of array1, array2

### best/worst case

2 misses every 4 i blocks of 4 array1[X] values loaded, then used 4 times before loading next block (and same for array2[X])

#### array1[i] and array2[i] same sets:

= distance from array1 to array2 is multiple of # sets  $\times$  bytes/set 2 misses every i block of 4 array1[X] values loaded, one value used from it, then, block of 4 array2[X] values replaces it, one value used from it, ...

#### worst case in practice?

two rows of matrix?

often sizeof(row) bytes apart

if the row size is multiple of number of sets  $\times$  bytes per block, oops!

2-way set associative, 2 byte blocks, 2 sets

## example replacement policies

actually works pretty well in practice

```
least recently used
     take advantage of temporal locality
     at least \lceil \log_2(E!) \rceil bits per set for E-way cache
           (need to store order of all blocks)
approximations of least recently used
     implementing least recently used is expensive
     really just need "avoid recently used" — much faster/simpler
     good approximations: E to 2E bits
first-in, first-out
     counter per set — where to replace next
(pseudo-)random
     no extra information!
```

### associativity terminology

direct-mapped — one block per set

E-way set associative — E blocks per set E ways in the cache

fully associative — one set total (everything in one set)

# **Tag-Index-Offset formulas**

m memory addreses bits number of blocks per set ("ways")

 $S=2^s$  number of sets

s (set) index bits

 $B=2^b$  block size

b (block) offset bits

t = m - (s + b) tag bits

 $C = B \times S \times E$  cache size (excluding metadata)

## Tag-Index-Offset exercise

m memory addreses bits (Y86-64: 64) E number of blocks per set ("ways")

 $S = 2^s$  number of sets s (set) index bits

 $B=2^b$  block size

b (block) offset bits

t = m - (s + b) tag bits

 $C = B \times S \times E$  cache size (excluding metadata)

#### My desktop:

L1 Data Cache: 32 KB, 8 blocks/set, 64 byte blocks

L2 Cache: 256 KB, 4 blocks/set, 64 byte blocks

L3 Cache: 8 MB, 16 blocks/set, 64 byte blocks

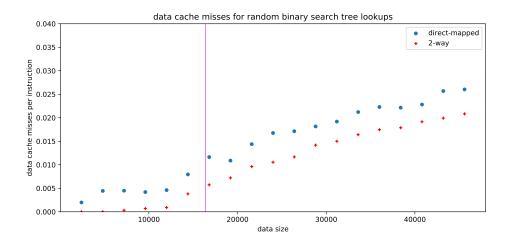

Divide the address 0x34567 into tag, index, offset for each cache.

### T-I-O exercise: L1

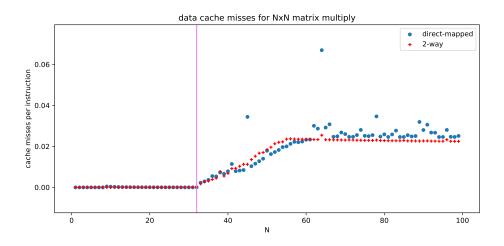

# T-I-O results

# T-I-O: splitting

# simulated misses: BST lookups

# simulated misses: matrix multiplies

# C and cache misses (warmup 4)

```
int array[8];
...
int even_sum = 0, odd_sum = 0;
even_sum += array[0];
even_sum += array[2];
even_sum += array[4];
even_sum += array[6];
odd_sum += array[1];
odd_sum += array[3];
odd_sum += array[5];
odd_sum += array[7];
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

How many data cache misses on a **2**-set direct-mapped cache with 8B blocks?

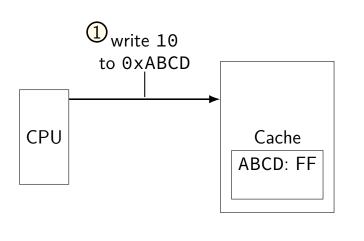

# arrays and cache misses (2)

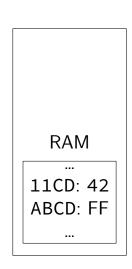

```
int array[1024]; // 4KB array
int even_sum = 0, odd_sum = 0;
for (int i = 0; i < 1024; i += 2)
    even_sum += array[i + 0];
for (int i = 0; i < 1024; i += 2)
    odd_sum += array[i + 1];</pre>
```

Assume everything but array is kept in registers (and the compiler does not do anything funny).

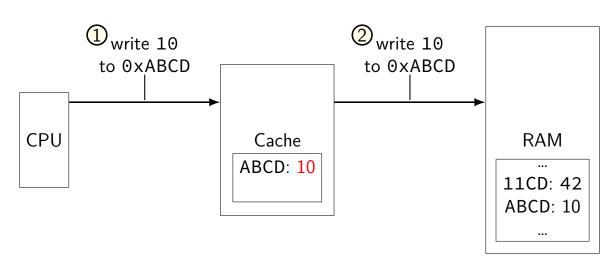

How many data cache misses on a 2KB direct-mapped cache with 16B cache blocks? Would a set-associtiave cache be better?

option 1: write-through

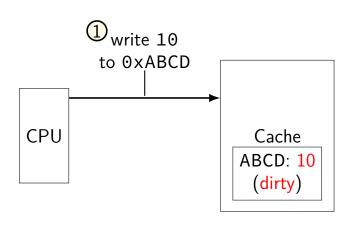

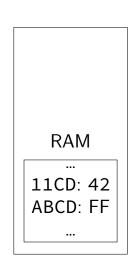

#### option 1: write-through

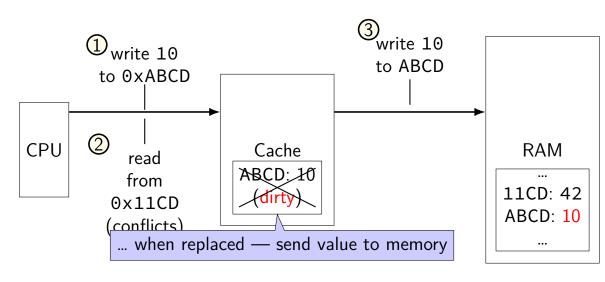

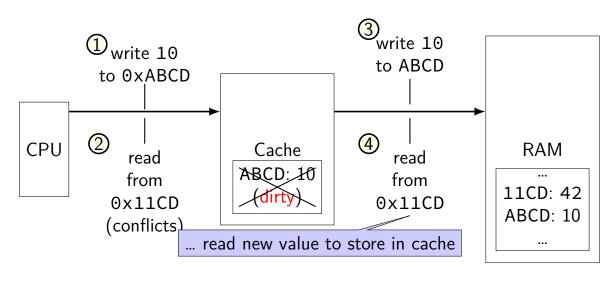

option 2: write-back

option 2: write-back

# writeback policy

changed value!

2-way set associative, 4 byte blocks, 2 sets

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1	000000	mem[0x00] mem[0x01]	0	1		mem[0x60]* mem[0x61]*		1
1	1	011000	mem[0x62] mem[0x63]	0	0				0

1 = dirty (different than memory) needs to be written if evicted

#### allocate on write?

processor writes less than whole cache block

block not yet in cache

two options:

#### write-allocate

fetch rest of cache block, replace written part (then follow write-through or write-back policy)

#### write-no-allocate

don't use cache at all (send write to memory *instead*) guess: not read soon?

2-way set associative, LRU, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1		mem[0x00] mem[0x01]	0	1		mem[0x60] mem[0x61]		1
1	1	011000	mem[0x62] mem[0x63]	0	0				0

writing  $\widehat{0x}FF$  into address 0x04? index 0, tag 000001

2-way set associative, LRU, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1		mem[0x00] mem[0x01]	0	1	011000	mem[0x60] mem[0x61]	* <b>1</b>	1
1	1		mem[0x62] mem[0x63]	0	0				0

writing 0xFF into address 0x04?

index 0, tag 000001

step 1: find least recently used block

2-way set associative, LRU, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1		mem[0x00] mem[0x01]	0	1	011000	mem[0x60] mem[0x61]	* <del>1</del>	1
1	1		mem[0x62] mem[0x63]	0	0				0

writing 0xFF into address 0x04?

index 0, tag 000001

step 1: find least recently used block

step 2: possibly writeback old block

2-way set associative, LRU, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1		mem[0x00] mem[0x01]	0	1	000001	0xFF mem[0x05]	1	0
1	1		mem[0x62] mem[0x63]	0	0				0

writing 0xFF into address 0x04?

index 0, tag 000001

step 1: find least recently used block

step 2: possibly writeback old block

step 3a: read in new block – to get mem[0x05]

step 3b: update LRU information

2-way set associative, LRU, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1	000000	mem[0x00] mem[0x01]	0	1	011000	mem[0x60] mem[0x61]	* 1	1
1	1	011000	mem[0x62] mem[0x63]	0	0				0

writing  $\widehat{0x}FF$  into address 0x04?

step 1: is it in cache yet?

step 2: no, just send it to memory

# exercise (1)

2-way set associative, LRU, write-allocate, writeback

index	valid	tag	value	dirty	valid	tag	value	dirty	LRU
0	1	001100	mem[0x30] mem[0x31]	0	1	010000	mem[0x40] mem[0x41]	* 1	0
1	1	011000	mem[0x62] mem[0x63]	0	1	001100	mem[0x32] mem[0x33]	* 1	1

for each of the following accesses, performed alone, would it require (a) reading a value from memory (or next level of cache) and (b) writing a value to the memory (or next level of cache)?

writing 1 byte to 0x33 reading 1 byte from 0x52 reading 1 byte from 0x50

# exercise (2)

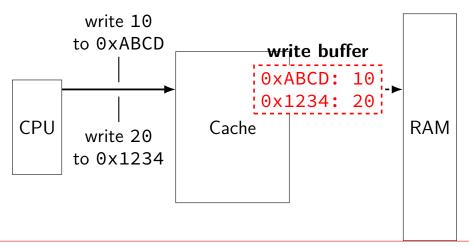

2-way set associative, LRU, write-no-allocate, write-through

index	valid	tag	value	valid	tag	value	LRU
0	1	001100	mem[0x30] mem[0x31]	1	010000	mem[0x40] mem[0x41]	0
1	1	011000	mem[0x62] mem[0x63]	1	001100	mem[0x32] mem[0x33]	1

for each of the following accesses, performed alone, would it require (a) reading a value from memory and (b) writing a value to the memory?

writing 1 byte to 0x33 reading 1 byte from 0x52 reading 1 byte from 0x50

#### fast writes

write appears to complete immediately when placed in buffer memory can be much slower

### cache miss types

common to categorize misses: roughly "cause" of miss assuming cache block size fixed

compulsory (or cold) — first time accessing something adding more sets or blocks/set wouldn't change

conflict — sets aren't big/flexible enough
a fully-associtive (1-set) cache of the same size would have done better

capacity — cache was not big enough

### making any cache look bad

- 1. access enough blocks, to fill the cache
- 2. access an additional block, replacing something
- 3. access last block replaced
- 4. access last block replaced
- 5. access last block replaced

...

but — typical real programs have locality

### cache optimizations

```
(assuming typical locality + keeping cache size constant if possible...)
                        miss rate hit time miss penalty
increase cache size
                        better
                                   worse
                                             worse?
increase associativity
                        better
                                   worse
increase block size
                        depends
                                   worse
                                             worse
add secondary cache
                                             better
write-allocate
                        hetter
writeback
LRU replacement
                                             worse?
                        better
prefetching
                        better
 prefetching = guess what program will use, access in advance
```

average time = hit time + miss rate  $\times$  miss penalty

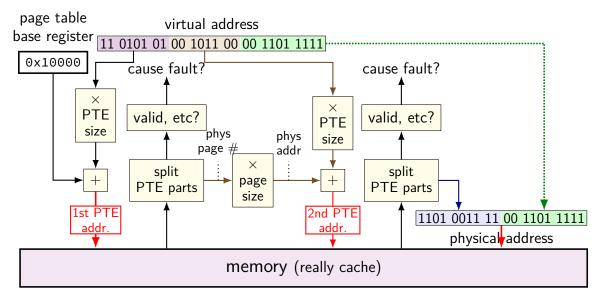

# cache optimizations by miss type

(assuming other listed parameters remain constant)			
	capacity	conflict	compulsory
increase cache size	fewer misses	fewer misses	
increase associativity	_	fewer misses	<del></del>
increase block size	more misses?	more misses?	fewer misses
LRU replacement	_	fewer misses	<del></del>
prefetching	_		fewer misses

#### another view

# two-level page table lookup

#### cache accesses and multi-level PTs

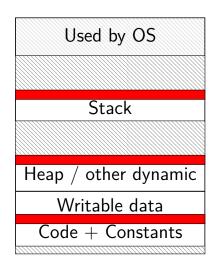

four-level page tables — five cache accesses per program memory access

L1 cache hits — typically a couple cycles each?

so add 8 cycles to each program memory access?

not acceptable

### program memory active sets

0xffff ffff ffff ffff 0xffff 8000 0000 0000

0x7F...

small areas of memory active at a time one or two pages in each area?

0x0000 0000 0040 0000

## page table entries and locality

page table entries have excellent temporal locality

typically one or two pages of the stack active

typically one or two pages of code active

typically one or two pages of heap/globals active

each page contains whole functions, arrays, stack frames, etc.

### page table entries and locality

page table entries have excellent temporal locality

typically one or two pages of the stack active

typically one or two pages of code active

typically one or two pages of heap/globals active

each page contains whole functions, arrays, stack frames, etc.

needed page table entries are very small

caled a **TLB** (translation lookaside buffer)

very small cache of page table entries

L1 cache	TLB	
physical addresses	virtual page numbers	
bytes from memory	page table entries	
tens of bytes per block	one page table entry per block	
usually thousands of blocks	usually tens of entries	

caled a **TLB** (translation lookaside buffer)

very small cache of page table entries

L1 cache	TLB	
physical addresses	virtual page numbers	
bytes from memory	page table entries	
tens of bytes per block	one page able entry per block	
usually thousands of blocks usually to be of entries only caches the page table lookup itself		
only caches th	only caches the page table lookup itself	
(generally) jus	(generally) just entries from the last-level page tables	

caled a **TLB** (translation lookaside buffer)

very small cache of page table entries

L1 cache	TLB	
physical addresses	virtual page numbers	
bytes from memory	emory page table entries	
tens of bytes per block	one page table entry per block	
usually thousands of blocks	usually tens of entries	

not much spatial locality between page table entries (they're used for kilobytes of data already) (and if spatial locality, maybe use larger page size?)

caled a **TLB** (translation lookaside buffer)

very small cache of page table entries

L1 cache	TLB	
physical addresses	virtual page numbers	
bytes from memory	page table entries	
tens of bytes per block	one page table entry per block	
usually thousands of blocks	usually tens of entries	
-		

few active page table entries at a time enables highly associative cache designs

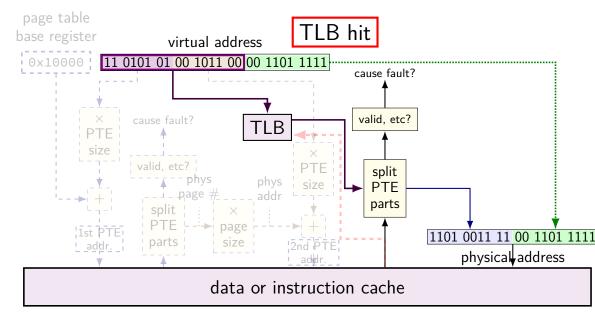

## TLB and multi-level page tables

TLB caches valid last-level page table entries

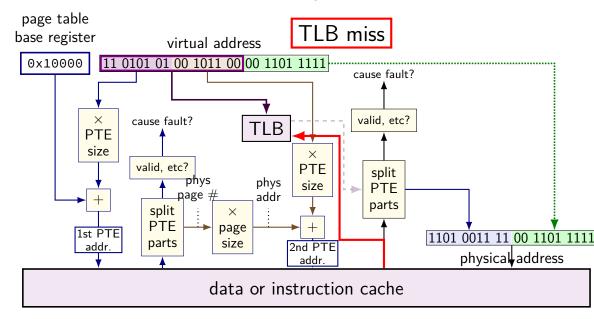

doesn't matter which last-level page table

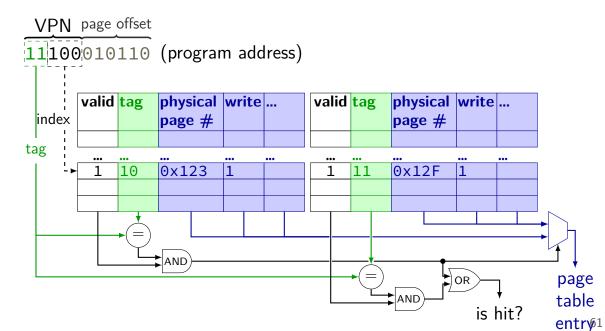

means TLB output can be used directly to form address

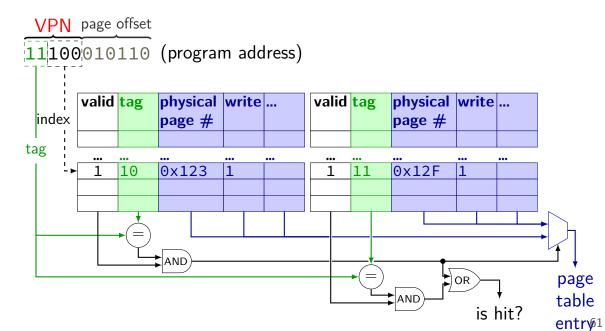

# TLB and two-level lookup

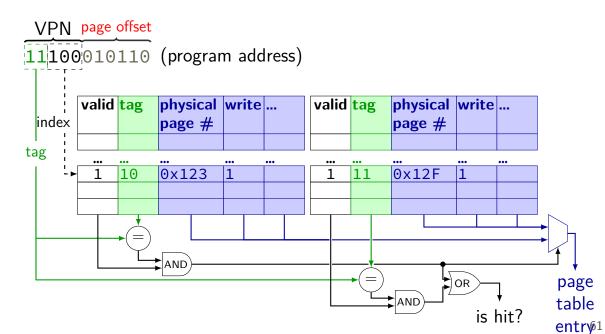

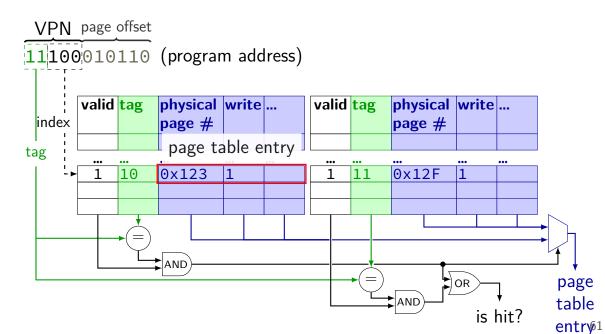

# TLB and two-level lookup

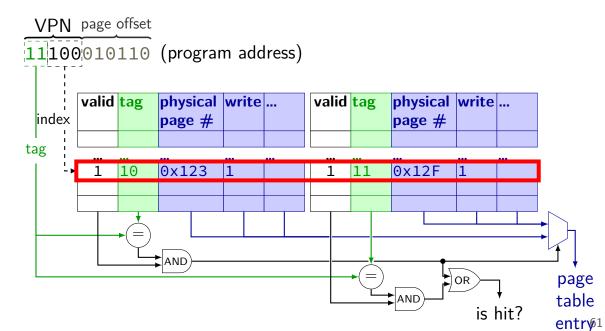

# address splitting for TLBs (1)

my desktop:

4KB ( $2^{12}$  byte) pages; 48-bit virtual address

64-entry, 4-way L1 data TLB

TLB index bits?

TLB tag bits?

# address splitting for TLBs (2)

my desktop:

4KB ( $2^{12}$  byte) pages; 48-bit virtual address

1536-entry  $(3 \cdot 2^9)$ , 12-way L2 TLB

TLB index bits?

TLB tag bits?

# exercise: TLB access pattern (setup)

4-entry, 2-way TLB, LRU replacement policy, initially empty

4096 byte pages

how many index bits?

TLB index of virtual address 0x12345?

## exercise: TLB access pattern

4-entry, 2-way TLB, LRU replacement policy, initially empty

4096 byte pages

type	virtual	physical
read	0x440030	0x554030
write	0x440034	0x554034
read	0x7FFFE008	0x556008
read	0x7FFFE000	0x556000
read	0x7FFFDFF8	0x5F8FF8
read	0x664080	0x5F9080
read	0x440038	0x554038
write	0x7FFFDFF0	0x5F8FF0

which are TLB hits? which are TLB misses? final contents of TLB?

### changing page tables

what happens to TLB when page table base pointer is changed? e.g. context switch

most entries in TLB refer to things from wrong process oops — read from the wrong process's stack?

### changing page tables

what happens to TLB when page table base pointer is changed? e.g. context switch

most entries in TLB refer to things from wrong process oops — read from the wrong process's stack?

option 1: invalidate all TLB entries side effect on "change page table base register" instruction

#### changing page tables

what happens to TLB when page table base pointer is changed? e.g. context switch

most entries in TLB refer to things from wrong process oops — read from the wrong process's stack?

option 1: invalidate all TLB entries side effect on "change page table base register" instruction

option 2: TLB entries contain process ID set by OS (special register) checked by TLB in addition to TLB tag, valid bit

### editing page tables

what happens to TLB when OS changes a page table entry?

most common choice: has to be handled in software

### editing page tables

what happens to TLB when OS changes a page table entry?

most common choice: has to be handled in software

invalid to valid — nothing needed TLB doesn't contain invalid entries MMU will check memory again

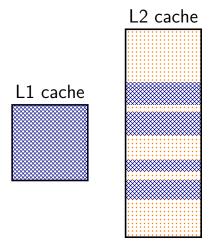

valid to invalid — OS needs to tell processor to invalidate it special instruction (x86: invlpg)

valid to other valid — OS needs to tell processor to invalidate it

#### inclusive versus exclusive

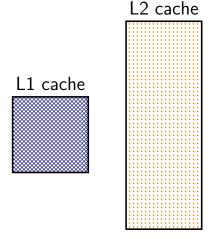

L2 inclusive of L1

everything in L1 cache duplicated in L2 adding to L1 also adds to L2

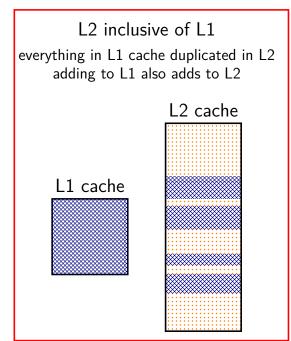

#### L2 exclusive of L1

L2 contains different data than L1 adding to L1 must remove from L2 probably evicting from L1 adds to L2

#### inclusive versus exclusive

#### 1.2 exclusive of 1.1

L2 contains different data than L1 adding to L1 must remove from L2 probably evicting from L1 adds to L2

inclusive policy: no extra work on eviction but duplicated data

easier to explain when  $\mathsf{L}k$  shared by multiple  $\mathsf{L}(k-1)$  caches?

#### inclusive versus exclusive

#### L2 inclusive of L1

everything in L1 cache duplicated in L2 adding to L1 also adds to L2

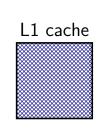

#### L2 cache

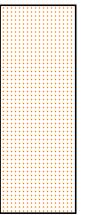

exclusive policy: avoid duplicated data sometimes called *victim cache* (contains cache eviction victims)

makes less sense with multicore

#### L2 exclusive of L1

L2 contains different data than L1 adding to L1 must remove from L2 probably evicting from L1 adds to L2 L2 cache

# Tag-Index-Offset formulas (direct-mapped)

(formulas derivable from prior slides)

$$S=2^s$$
 number of sets

$$s$$
 (set) index bits

$$B = 2^b$$
 block size

$$m$$
 memory addreses bits

$$t = m - (s + b)$$
 tag bits

$$C = B \times S$$
 cache size (if direct-mapped)
