parallelization and performance

suppose we have 1000 time units of computation to do

with 100 cores, how fast?

parallelization and performance

suppose we have 1000 time units of computation to do

with 100 cores, how fast?

if “only” 99% can be parallelized?

parallelization and performance

suppose we have 1000 time units of computation to do

with 100 cores, how fast?

if “only” 99% can be parallelized?

if we need to spend 2 time units coordinating threads?

parallelization and performance

suppose we have 1000 time units of computation to do

with 100 cores, how fast?

if “only” 99% can be parallelized?

if we need to spend 2 time units coordinating threads?

if we can’t split the computation evenly?

aside: Amdahl's Law

performance gain limited to part we can speed up

we'll quickly hit "diminishing returns" for any optimization

- part we can't speed up becomes much bigger portion after optimization
