

connecting things

how to (in hardware) connect A and B?

A

B

connecting things

how to (in hardware) connect A and B?

one wire carrying binary signals?

A

B

connecting things

how to (in hardware) connect A and B?

connecting things

how to (in hardware) connect A and B?

connecting things

how to (in hardware) connect A and B?

...and later

taking turns, but one-way
called *half-duplex*
challenge: how to agree who's turn?

connecting things

how to (in hardware) connect A and B?

both ways at the same time
called *full duplex* (or *duplex*)

connecting things

how to (in hardware) connect A and B?

here: duplex via multiple wires (simplest scheme)
can achieve effect electrically/etc. via one wire
example: cable Internet
(how is topic for ECE class)

F

how to connect?

connecting things

all-to-all

connecting things

connecting things

shared bus, really?

common for parts of internals of computers (topic later)

model for wifi

radio “channel” kinda similar to shared wire

how the early versions of Ethernet worked

“vampire taps” physically attached to shared cable

shared bus, messages for who?

messages need a '*header*' to tell who it's to/from

everyone needs to filter out messages that aren't theirs

Figure 6-1: Data Link Layer Frame Format

taking turns on shared bus?

token ring

- one machine has a 'token' = can send
- send special message to pass to another machine

free-for-all: collision detection + retry

- detect if you're transmitting when someone else is
- wait (usually randomized amount of time) and retry

coordinating machine transmits timeslots

- part of common cellphone design (TDMA: time division multiple access)

make bus support multiple transmitters?

- requires understanding how interference works
- another part of common cell phone design

connecting things

what does the hub do?

simple version:

- imitate shared bus: copy messages to everyone else
- something to handle two messages sent at once

less simple:

- read “header” on message + send to destination only
- requires some way to figure out destinations
- queue of messages waiting to be sent

connecting things

more complicated designs

hierarchies

networks of networks

“internetworks”

so far still have single points of failure

connecting things

individual computers are networks

individual computers are (kinda) networks of...

- processors

- memories

- I/O devices

so what topology (layout) do those networks have?

the “bus”

example: 80386 signal pins

name	purpose	
CLK2	clock for bus	timing
W/R#	write or read?	metadata
D/C#	data or control?	
M/IO#	memory or I/O?	
INTR	interrupt request	
...	other metadata signals	
BE0#-BE3#	(4) byte enable	address
A2-A31	(30) address bits	
DO-D31	(32) data signals	data

example: AMD EPYC (1 socket)

Fig. 21. Single-socket AMD EPYC™ system (SP3).

Figure from Burd et al,
" 'Zeppelin': An SoC for Multichip Architectures" (IEEE JSSC Vol 54, No 1)

example: Intel Skylake-SP

Figure from Tam et al, "SkyLake-SP: A 14nm 28-Core Xeon® Processor" (ISSCC 2018)

extra trips to CPU

connecting devices

connecting devices

connecting devices

control registers might not really be registers
e.g. maybe writing to write? “control register”
actually just sends the value the external hardware
